The *ſecond* period begins with the ſiege of Troy, and terminates with the battle of Marathon, 490 B.C., including about 694 years. In the year 1104 B.C., 80 years after the taking of Troy, the Heraclidæ, or deſcendants of Hercules, conducted the Dorians to the eaſtern coaſt of Peloponneſus, and having landed their followers without oppoſition, aſſailed the defenceleſs territories, to which they had long ſaid claim, comprehending the whole peninſula, except the central province of Arcadia, and the maritime diſtrict of Achaia. The five other provinces were conquered at the ſame time, though by different means. Laconia was betrayed to the invaders; Argos acknowledged their authority; Corinth, Elis, and Meſſenia ſubmitted to their arms. The revolution was complete, and effected with little bloodſhed; but not without great oppreſſion of the ancient inhabitants, many of whom emigrated, and many were reduced to ſlavery. The Heraclidæ divided their new acquiſitions by lot. Upon the diviſion of Peloponneſus the kingdom of Lacedæmon commenced, 1102 B.C. In the year 1096 B.C., or 88 years after the taking of Troy, the Eolians, having traverſed the northern parts of Græcia in queſt of new ſettlements, croſſed the Helleſpont, and eſtabliſhed themſelves along the ſhore of the ancient kingdom of Priam. They gradually diffuſed their colonies from Cyzicus on the Propontis to the mouth of the river Hermus; which delightful country, together with the iſle of Leſbos, from this time received the name of Eolis or Eolia, denoting that its inhabitants belonged to the Eolian branch of the Hellenic race. In the year 1070 B.C. royalty terminated in Athens upon the death of Codrus, and the Athenians were afterwards governed by Archons. In the year 1044 B.C., 60 years after the return of the Heraclidæ, the Ionians, blended with other emigrants, having ſeized the central and moſt beautiful part of the Aſiatic coaſt, gradually diffuſed their colonies from the banks of the Hermus to the promontory of Poſidion, and afterwards took poſſeſſion of Chios and Samos; and all theſe countries were united in the year above-mentioned by the name of Ionia, intimating that the Ionians compoſed the moſt numerous diviſion of the colony. (See Ionia.) The Doric migration took place in the year B.C. 944 (See Doris.)

During the heroic ages we have ſeen, in the preceding part of this article, that the authority of kings was founded on religion, ſupported by gratitude, and confirmed by utility. While they approved themſelves worthy miniſters of heaven, they were entitled to due and hereditary honours; but they were bound to reſpect the rights, the ſentiments, and even the prejudices of their ſubjects. But at length, in-[illegible] by ambition and avarice, they tranſgreſſed the preſcribed limits, and trampled on thoſe laws which their predeceſſors had held ſacred. The minute diviſion of property, which had taken place, not only in Peloponneſus, but in the northern provinces of Greece, rendered the nobles and people more ſenſible of their encroachments, and induced them to reſiſt their oppreſſors. The more independent and illuſtrious citizens, who from the earlieſt times had been accuſtomed to come armed to the council or aſſembly, communicated their grievances, and adopted proper means for removing them. Miltas, the fourth Argive prince in ſucceſſion to Temenus, to whom Argos fell on the Heraclidan diſtribution, was condemned to death for uſurping abſolute power. In Attica monarchy more honourably expired; it periſhed ſtill more diſgracefully in Arcadia; but was gradually aboliſhed in every province of Greece, except Sparta, from the ſouthern extremity of Peloponneſus to the northern frontier of Theſſaly. The conſequence of the abolition of monarchy was the introduction of accumulated evils. Theſe, however, were removed, or at leaſt alleviated, by the authority of the Amphictyonic council, and by that of the oracles, particularly that of Delphi. This latter oracle confirmed by its awful ſanction the Olympic games and Spartan laws, which had been reſpectively eſtabliſhed, the former by Iphitus, and the latter by Lycurgus in the ſame year, *viz.* 884 B.C.; and which ſerved to the ſafety of their reſpective territories, though in different ways; the Olympic games by rendering Elis the moſt pacific, and the laws of Lycurgus by making Sparta the moſt warlike, of all the Grecian communities. Greece, even under its kings, was divided into many independent ſtates; and under the republican form of government it was ſtill more ſubdivided; and hence wars became more frequent, and battles more bloody and more obſtinate. But the long and ſpirited conteſt between the Lacedæmonians and Meſſenians was the only war of that age which produced permanent effects. Of Laconia and Meſſenia we ſhall give an account under their reſpective articles. We ſhall here obſerve, that they were both governed by kings of the family of Hercules, and inhabited by ſubjects of the Doric race, and yet this kind of mutual affinity and connection was not ſufficient to counteract other cauſes, which produced hoſtilities among them. Urged by reciprocal provocations which we cannot here detail, the Spartans invade the Meſſenian frontier and attack the ſmall town of Amphica; and thus in the year 743 B.C. began the firſt war between the Meſſenians and Lacedæmonians, which laſted 19 years, and terminated with the ſurrender of Ithome, their capital, to the Lacedæmonians, and the diſperſion of its inhabitants. In the year 685 B.C. the Meſſenians prepare to revolt, and a ſecond war commences, which continued 14 years, and ended with the capture of Ira, or Eira, by the Lacedæmonians, after a ſiege of 11 years. The conqueſt of Meſſenia rendered Sparta the moſt conſiderable power in Greece, as its ſubjects occupied two-fifths of the Peloponneſus. In the year B.C. 600 commenced the firſt "Sacred War," occaſioned by an injury committed againſt the oracle of Delphi, and undertaken by order of the Amphictyons, and terminated by the total deſtruction of the cities accuſed of ſacrilegious outrage. On occaſion of the happy termination of this war the Pythian games were re-eſtabliſhed 591 B.C. The battle of Marathon, which cloſes this ſecond period of the Grecian hiſtory, terminated, after a very ſevere conteſt, in the total defeat of the Perſians, and triumph of the Athenians under their commander Miltiades.

The *third* period of the hiſtory of Greece comprehends an interval of 167 years, that elapſed between the battle of Marathon and the death of Alexander, 323 B.C. The Athenians, in compliance with the advice of Themiſtocles, augment their navy; and under his command they defeat the fleets of Ægina and Corcyra. Themiſtocles, inſtead of allowing the Athenians to indulge themſelves in ſecurity after the advantages they had gained, exhorted them to be always ready for action. In conſequence of this judicious counſel, they were enabled to oppoſe the immenſe armaments of Xerxes. The Athenian fleet proved the ſafe-guard of Greece, and prevented a country, from which the knowledge of laws, learning, and civility was deſtined to flow over Europe, from becoming a province of the Perſian empire, and being confounded with the maſs of barbarous nations. Xerxes was provided with 1200 ſhips of war, and 3000 ſhips of burthen, for his intended expedition: and his army conſiſted of ſeventeen hundred thouſand infantry, and four hundred thouſand cavalry, and theſe, joined to thoſe who manned his fleet, amounted to near two millions of fighting men. In the year 480 B.C. he paſſed the Helleſpont, and the vainglorious monarch had the pleaſure of reviewing the whole fleet and army near Doriſcus, a city of Thrace, at the mouth of the river Hebrus. In the mean while thoſe Grecians, who, unmoved by the terrors of invaſion, obeyed the voice of liberty and their country, had ſent deputies to the iſthmus of Corinth, to deliberate about the common ſafety. A general union prevailed, and the general danger ſeemed to harmonize the moſt diſcordant members of the common council. The Grecian fleet ſailed to Artemiſium, patiently expecting the arrival of the barbarians. The ſtraits of Thermopylæ, 15 miles diſtant from the ſtation of the Grecian fleet at Artemiſium, and deemed the gate or entrance into Greece, was guarded by troops, conſiſting chiefly of Peloponneſians, under the command of Leonidas, the Spartan king. Xerxes having made his previous arrangements, ſent meſſengers to treat with the Spartans, and to deſire them to lay down their arms; to which they replied, "Let him come and take them." The meſſengers then offered them lands, on condition of their becoming allies to the great king, but they anſwered: "That it was the cuſtom of their republic to conquer lands by valour, not to acquire them by treachery." Xerxes waited four days after the return of the meſſengers, expecting the Grecians to retreat into their own country, or ſurrender their arms. On the fifth day he determined to chaſtiſe their inſolent oppoſition. The attack was ordered, and the Perſians were repelled: it was renewed the next day with the like reſult.

The Greeks, however, were betrayed by Epialtes, a perfidious wretch of their own nation, who conducted a body of twenty thouſand Perſians through a paſſage in the mountains of Oeta, ſeveral miles to the weſt of that guarded by Leonidas. The Athenian general had prudently guarded this important but unknown paſs, which, as he conceived, chance or treachery might diſcover to the Perſians. A body of 1000 Phocians had been appointed to this ſervice; upon the approach of the Perſians they inſtantly flew to their arms, and determined to reſiſt the progreſs of the enemy or to die in the attempt. Expecting to be purſued, they retired to the higheſt part of the mountain; but the Perſians, declining to follow them, ſeized the paſſage which they had abandoned, and marched down the mountain in order to accompliſh the deſign which had been preconcerted by the traitor Epialtes. Leonidas, apprized of this act of treachery, called a council of war; when all the confederates of Peloponneſus, except the Spartans, determined to abandon a poſt which they deemed to be untenable. Leonidas, however, with 700 Theſpians, 400 Thebans, and 300 Spartans, remained in the poſt of danger and of glory. In the dead of night the Spartans, headed by Leonidas, marched in a cloſe battalion towards the Perſian camp, with reſentment heightened by deſpair. The conflict was ardent and deſtructive, whilſt the Greeks were favoured in their attack by the darkneſs of the night; but at the approach of day the Perſians, who had previouſly fled, diſcovered that their fears had multiplied the number of the enemy; and therefore rallying their ſcattered forces, Xerxes gave orders to purſue the Greeks, who had retreated in cloſe order to the ſtraits of Thermopylæ. The ſhock was dreadful; and the battle was maintained on the ſide of the Greeks with perſevering intrepidity and deſperate valour. At length a barbarian dart pierced the heart of Leonidas; nevertheleſs the Lacedæmonians and Theſpians, though ingloriouſly deſerted by the Thebans, maintained their firmneſs to the laſt; and they were finally not deſtroyed or conquered, but buried under a trophy of Perſian arms. (See LEONIDAS and THERMOPYLÆ.) During the military operations at Thermopylæ, the Grecian fleet was ſtationed in the harbour of Artemiſium, the northern promontory of Eubœa, and the numerous one of the Perſians had anchored on the road that extends between the city of Caſtanæa and the promontory of Sepias, on the coaſt of Theſſaly. Here it ſuffered calamities, of which Xerxes had been forewarned, but which he diſregarded. Themiſtocles, by his addreſs, prevailed on the Athenian commander to remain at Artemiſium; and as ſoon as the Perſians recovered from the terrors of the ſtorm, the effects of which they had ſuffered, both ſides prepared for a battle, for the reſult of which ſee ARTEMISIUM. The Perſians were again totally defeated near Salamis (which ſee); upon which Xerxes determined to leave Greece. Of the conduct of Themiſtocles on this occaſion, ſee his article; and for an account of the battle of Platæa, ſee PLATÆA. The event of this bloody engagement not only delivered the Greeks from the danger of ſervitude, but gave them poſſeſſion of greater wealth than they could ever have expected to poſſeſs. In his precipitate retreat from Greece, Xerxes left behind him all his riches and magnificence. The battle of Platæa was ſucceeded by that of Mycalé, in which the Greeks were again victorious. About 40,000 Perſians periſhed in the field, many fell in the purſuit, and the remainder fled in diſorder, nor thought themſelves ſecure till they had reached the walls of Sardis. Their ſhips, their camp, the freedom of Ionia, and the undiſturbed poſſeſſion of the Aſiatic coaſt, formed the ineſtimable prize of the victors; and thus the expedition of Xerxes, undertaken with a view to enſlave Europe, reſtored liberty to the faireſt portion of Aſia. The beginning of the 5th century B.C. forms the moſt glorious era in the hiſtory of Greece. It is, however, the peculiar glory of the Athenians that, during their rapid career of military and naval triumphs, they cultivated, with a generous enthuſiaſm, the arts which adorn peace as well as war. It is obſervable that in the ſingle life-time of Pericles, the republic of Athens produced thoſe ineſtimable models of poetry, eloquence, and philoſophy, which, in every ſucceeding age, the enlightened portion of mankind hath invariably regarded as the beſt ſtandards, not merely of compoſition and ſtyle, but of taſte and reaſon. The name of Greek ſeemed thenceforth to be ſunk in that of Athenian. (See ATHENS, and SPARTA.) For an abſtract of the further hiſtory of this period of Alexander's hiſtory and exploits, we have given a brief ſketch under his article; we ſhall here obſerve, with Dr. Gillies, that during the latter years of his reign the Greeks, deprived of the honour and delivered alſo from the cares of independent ſovereignty, and undiſturbed by thoſe continual and often bloody diſſenſions, which deform the annals of their tumultuous liberty, indulged their natural propenſity to the ſocial embelliſhments of life; a propenſity by which they were honourably diſtinguiſhed above all other nations of antiquity. Their innumerable ſhows, feſtivals, and dramatic entertainments, were exhibited with more pomp than at any former period. The ſchools of philoſophers and rhetoricians were frequented by all deſcriptions of men. Painting and ſtatuary were cultivated with equal ardour and ſucceſs. Many improvements were made in the ſciences, and the Greeks, particularly the Athenians, ſtill rivalled the taſte and genius, though not the ſpirit and virtue, of their anceſtors. Yet even in this degenerate ſtate, when patriotiſm and true valour were extinct, and theſe vanquiſhed republicans had neither liberties to love, nor country to defend, their martial honours were revived, and brightened by an aſſociation with the renown of their conqueror. Under Alexander, their exploits, though directed to very different purpoſes, equalled, perhaps excelled, the boaſted trophies of Marathon and Platæa. By a ſingularity peculiar to their fortune, the era of their political diſgrace coincides with the moſt ſplendid period of their military glory. Alexander was himſelf a Greek; his kingdom had been founded by a Grecian colony; and to revenge the wrongs of his nation, he undertook and accompliſhed the moſt extraordinary enterpriſes recorded in the hiſtory of the world.

The *fourth* period of the hiſtory of Greece, commencing with the death of Alexander, 323 B.C. and terminating 146 B.C. when the Achæan league was diſſolved, and Greece became a Roman province, under the name of Achaia, comprehends an interval of 177 years. After various changes and revolutions, for an account of which, ſee ACHÆANS and ATHENS, it became ſubject to the Turks.

GRÆCIA, *Magna*, a name given to the ſouthern part of Italy, comprehending Apulia, Lucania, and the country of the Brutii, and alſo to Sicily and ſeveral of the adjacent iſlands. The name of *Græcia* was derived from the Greek colonies, which migrated hither at different periods, and the epithet *magna*, or great, was derived from mere oſtentation, as Pliny informs us (l. iii. c. 5.). This migration and ſettlement took place at a very early period, about 1055 years B.C. The moſt numerous colonies, the migration of which was occaſioned by inteſtine faction, foreign invaſion, or the reſtleſs ſpirit of adventure and rapine, occupied the iſles of the Ionian and Ægean ſeas, the ſouthern coaſt of Italy almoſt interſected by the former, and the winding ſhores of Aſia Minor ſo beautifully diverſified by the latter. The larger iſlands of Sicily, Sardinia, and Cyprus were very anciently planted by Greeks.

Whoever has obſerved the deſolate barbarity of Calabria, or reflected on the narrow extent and preſent weakneſs of Sicily, will ſcarcely believe, that five centuries B. C. thoſe countries contained above 20 warlike communities, ſeveral of whom could ſend into the field 100 thouſand fighting men. In order to account for this wonderful population, we muſt look back to the period above mentioned in the heroic ages; and conſider likewiſe that the greater number of Greek colonies in thoſe parts were planted during the eighth century before the Chriſtian era, and chiefly, 1. By the Eubœans, whoſe principal city Chalcis, uſually furniſhing the conductor of the colony, gave the epithet of Chalcidian to the new ſettlements; 2. By the Achæans of Peloponneſus, who were of the Eolian tongue and lineage; and 3. By the Dorian ſtates of that peninſula, eſpecially Corinth. Beſides their powerful colonies in Corcyra, Leucas, Anactorium, Ambracia, whoſe tranſactions form ſuch an important part of the hiſtory of ancient Greece, the Corinthians founded Syracuſe, which ſoon became, and long continued, the capital of Sicily; and in the ſixth century B. C. the Syracuſans had extended their ſettlements over all the ſouthern coaſt of the iſland. By means of theſe and ſimilar eſtabliſhments of a powerful kind, the Dorians acquired, and always maintained, an aſcendant in Sicily; but the Achæan colonies, who were of the Æolian blood and language, commanded the Italian ſhore. Crotona, the moſt conſiderable city of the Achæans, and of all Italy in ancient times, was built 710 years B. C. Sybaris, its rival, was founded about the ſame time. The former ſent colonies to Tirina, Cephalonia, and Pandoſia; the latter built Laus, Metapontum, and Poſidonia, or Pæſtum, whoſe admired ruins atteſt the ancient wealth and grandeur of the Greek cities of Italy. We may here remark, that the Ionians, who came from Eubœa, and ſettled chiefly near the eaſtern ſhore of Sicily, never rivalled the power and fame of their Dorian and Æolian neighbours, but fell ſhort of thoſe nations in Magna Græcia, as much as they ſurpaſſed them on the ſhores and iſlands of Aſia. In order to account for the flouriſhing ſituation of Magna Græcia about the year 500 B. C., many cauſes may be aſſigned, beſides thoſe of a phyſical and moral nature, which uſually contribute to the rapid growth of newly-eſtabliſhed colonies. We might mention the natural fertility of Magna Græcia, and particularly of Sicily, which in many places produced an hundred fold; and in this connection obſerve, that the Greeks who failed thither from Peloponneſus, carried with them the knowledge and practice of agriculture, which had early attained a high degree of perfection in their peninſula; and that the exuberant ſoil of Sicily, improved by cultivation, ſoon exhibited a picture of that rich abundance, which, in later times, made that beautiful iſland be entitled the granary of Rome. Beſides, the peculiar ſituation of the Achæans and Dorians, from whom chiefly the colonies in Magna Græcia derived their origin, had a conſiderable influence in accelerating the population and grandeur of theſe new eſtabliſhments. The impartial and generous ſpirit of the Achæan laws early compenſated the natural defects of their territory, which was a long, but narrow, ſtrip of ground, not more fertile than extenſive, along the Corinthian gulf. They, however, were the firſt, and long the only republic of Greece, who admitted ſtrangers into their community on equal terms with the ancient citizens. The equitable and generous policy, which they tranſported with them into Magna Græcia, could not fail to promote the happineſs and proſperity of that delightful country. The condition of the Dorians, at the time when they planted colonies in Italy and Sicily, is not leſs worthy of conſideration. The Dorian ſtates of Peloponneſus were then univerſally ſubject to the gentle government of limited but hereditary princes, or to magiſtrates choſen from the deſcendants of their ancient royal families; and who, thus adorned by birth, were ſometimes ſtill more ennobled by wiſdom and virtue. Moreover, the colonies in Magna Græcia, enjoying a wide extent of territory before them, were not retarded in their advancement by interference of intereſt on the part of neighbouring ſtates, but they found ſufficient employment in ſubduing the original inhabitants of that country, without commencing hoſtilities either againſt their neighbours or againſt each other. The kings or nobility of Magna Græcia, ſecure of their own pre-eminence, felt nothing of the republican jealouſies which prevailed in the mother country. They received with pleaſure new citizens, or rather ſubjects, from whatever quarter they might come. The ſtates of Italy and Sicily, thus increaſing by degrees, could ſoon boaſt, the former of Crotona, Tarentum, Sybaris, Rhegium; the latter of Syracuſe, Agrigentum, Meſſené, Himera, and ſeveral other cities, which rivalled or ſurpaſſed the wealth of Athens or Corinth; and the populouſneſs of Thebes, Argos, or Sparta. The wars, conqueſts, or oppreſſions, and, above all, the civil diſſenſions, which in the ſixth century B. C. diſturbed and deformed the coaſt of Ionia, and the other Grecian colonies in the iſlands and continent of Aſia, brought frequent acceſſions of inhabitants to the ſhores of Magna Græcia. Nevertheleſs, the Ionians, along with their poetry, muſic, and painting, communicated alſo their diſſolute and artificial appetites to the Greeks of Italy and Sicily. It is a fact, however, that Magna Græcia, having obtained opulence by induſtry, diſſipated it in idleneſs and licentiouſneſs: inſomuch that the Greek cities of Italy, and particularly Sybaris and Crotona, fell a prey to the moſt dangerous errors and vices, when Pythagoras came to their relief about 550 years before the Chriſtian era. His philoſophy and legiſlation reformed and improved the manners and policy of Magna Græcia, and contributed, in an eminent degree, not only to the quiet and happineſs, but to the induſtry, power, and ſplendour of that celebrated country. (See PYTHAGORAS.) The concurring teſtimony of hiſtorians aſſures us, that the ſchool of Pythagoras flouriſhed above 40 years to the unſpeakable benefit of Magna Græcia when a war aroſe between Crotona and Sybaris, the latter of which had ever contemptuouſly rejected the Pythagorean inſtitutions.

Having traced the progreſs towards proſperity and renown of Magna Græcia, it is natural to ſtate the cauſes of its decay. In Italy, the citizens of Crotona had too ſoon reaſon for lamenting their inſurrection againſt their magiſtrates, and their dereliction of the diſcipline of Pythagoras. The other Greek cities of Italy, which are ſaid to have imitated the fatal example of Crotona, were haraſſed by wars againſt each other, or againſt their barbarous neighbours. In 60 years after the death of Pythagoras, an attempt was made to revive his inſtitutions; but in leſs than 40 years a new perſecution entirely drove the Pythagoreans from Italy, and completed, according to Polybius (i. 403.) the confuſion and miſery of that once happy country. Gillies's Hiſt. of Greece, vol. ii.

GRÆCINUS, JULIUS, in *Biography*, a Roman ſenator, who flouriſhed in the reign of Caligula, was ſon of a Roman knight, and greatly diſtinguiſhed for eloquence, and for the ſtudy of philoſophy, and he carried into practice the moral leſſons which his ſtudies led him to contemplate. He refuſed to obey the command of the emperor to appear as the accuſer of Marcus Silanus, and ſuffered death in conſequence. Seneca ſays of him, that he was put to death for the ſole reaſon, that he was too good a man to be permitted to live under a tyrant. He is mentioned by Columella, as having written a treatiſe concerning agriculture and the management of vines. He was the father of the illuſtrious Cn. Julius Agricola. Univer. Hiſt.

GRAEDER FIORD, in *Geography*, a bay of Weſt Greenland. N. lat. 63° 50′. W. long. 49° 30′.

GRAEMSAY, one of the Orkneys, a flat, fertile iſland, 1½ mile in length, and a mile in breadth, containing 32 families and 179 inhabitants; 1½ mile S. of Stromneſs, near the northern extremity of Hoy. The ſoil of the interior part is thin and fertile; but the coaſt is a chain of broken and pointed rocks. It contains a bed of ſlate, but no fuel.

GRAEN, a town of Hindooſtan, in Viſiapour; 24 miles S. of Currer.

GRAESATZ, a town of Croatia; 30 miles S. of Bihacs.

GRÆVIUS, JOHN-GEORGE, in *Biography*, an eminent critic; was born at Naumberg, in Saxony, in 1632. Having acquired a good knowledge of the learned languages in Germany, he went to Leipſic and ſtudied under Rivinus and Strauchius. After this he paſſed two years at Deventer, intimately connected with the celebrated Gronovius, to whom he acknowledged himſelf indebted for a conſiderable part of his acquiſitions, and whom he after ſucceeded in his profeſſorſhip. (See GRONOVIUS.) His great reputation induced the States of Utrecht to invite him to their univerſity, and during forty-one years he inſtructed the young men there in politics, hiſtory, and eloquence, refuſing various invitations to other ſeminaries. He died in the year 1703, at the age of ſeventy-one. He was the editor of many of our beſt claſſical authors, as Heſiod, the greater part of the works of Cicero, Florus, Cæſar, Suetonius, &c. He compiled alſo "Theſaurus Antiquitatum Romanorum," in 12 vols. fol. and "Theſaurus Antiquitatum Italicorum," in 6 vols. fol. This work was continued by Burman to the forty-fifth volume. Grævius, as a critic, was modeſt, and free from pride and pedantry, which are ſaid too frequently to accompany this character. Moreri.

GRAF, in *Geography*, one of the ſmaller Weſtern iſlands of Scotland, on the W. coaſt of Lewis. N. lat. 58° 14′. W. long. 6° 53′.

GRAFFENBERG, a town of Germany, in the territory of Nuremberg; 11 miles S. E. of Forcheim.—Alſo, a town of Upper Carniola; 19 miles S. E. of Laybach.

GRAFFENECK, a town of Auſtria; 10 miles S.W. of Sonneberg.

GRAFFER, from the French *greffier*, i. e. *ſcriba*, a *notary*, or *ſcrivener*. It is uſed in the ſtat. 5 Hen. VIII. cap. 1.

GRAFFIGNY, FRANCIO D'ISSEMBOURG D'HAPPONCOURT DE, in *Biography*, a literary lady, daughter of a major of the gendarmerie of the duke of Lorrain, was born at Nanci about the year 1694. She married de Graffigny, chamberlain to the duke, a man of violent paſſions and moſt brutal diſpoſition, from whom ſhe obtained, after living with him many years, a legal ſeparation. She now went to Paris with mademoiſelle de Guiſe, who was eſpouſed to marſhal Richelieu, and ſoon made her merit known to the wits of the capital. In 1745 ſhe was announced as the author of a Spaniſh novel. This was followed by the "Lettres d'une Peruvienne," in two vols. 12mo. which were much read and admired, though defective in point of ſtyle, and in the metaphyſical manner of treating of the paſſion of love. One of her beſt pieces was entitled "Cenie," a drama in five acts, which was written in proſe. She wrote another, which was entitled "La Fille d'Ariſtide," and which obtained a much leſs ſhare of public approbation. This lady was of a truly eſtimable character in private life, and had many reſpectable friends, even in the higheſt ranks of ſociety. The emperor and empreſs honoured her with particular notice, and made her frequent preſents. She was an aſſociate of the academy of Florence; and died at Paris in 1758, at the age of ſixty-four. Gen. Biog.

GRAFFIO, or GRAVIO, in our *Old Writers*, denotes a *landgrave* or *earl*. "Nec princeps nec graffio, hanc lenitatem mutare audeat."

GRAFFIUM, is uſed for a writing-book, regiſter, or chartulary of deeds and evidences.

GRAFT, in *Gardening*, a name applied to the ſhoot or ſcion that is to be inſerted into the ſtock or branch of the tree, in the operation of grafting. It has occaſionally the vulgar term of *graff* given it by gardeners.

The word is formed of the French *graffe*, which ſignifies the ſame thing; and *greffe*, in this ſenſe, is ſuppoſed to have been derived from the reſemblance the ſhoot bears to the point of a penknife, which was anciently called *greffe*. Du Cange goes farther, and derives the ancient *greffe* from *graphiolum*: Menage, from *graphium*, a Latin word, ſignifying a little ſtyle, or iron bodkin, one end whereof was pointed, and ſerved to write on waxen tablets; and the other flat, ſerving to efface or rub out what was written.

There are ſeveral circumſtances to be attended to in chooſing the grafts. The ſhoots or ſcions that are to be employed in this way, ſhould be ſelected and cut in the manner that will be directed in ſpeaking of grafting; but they ſhould never be taken from ſuch as have a too luxuriant growth, or are in the leaſt degree infected with diſeaſe of any kind. See GRAFTING.

In the conducting of this proceſs, though the veſſels of the ſtock, and thoſe of the ſhoot or graft are, in ſome meaſure,

ſure, brought into contact and thereby united, as well as thoſe of the latter ſupplied with nutritious matters from the former, yet their economy remains ſtill the ſame. Mr. Bradley has conſidered it as a ſort of planting; the ſhoot or ſcion rather taking root in the ſtock or tree into which it is inſerted, than uniting itſelf with it, as is ſeen by its preſerving its natural purity and utility, although fed and ſupported merely by a crab-ſtock; which it is ſuppoſed depends upon ſome difference in the veſſels of the ſhoot or ſcion from thoſe of the ſtock or tree.

GRAFTING, the act of inſerting a ſhoot or ſcion taken from one tree, into the ſtem or ſome other part of another, in ſuch a manner as to unite and conſtitute a perfect plant of the ſame kind as that from which the branch was taken.

It is by this practice that particular ſorts of curious fruit-trees of different kinds are capable of being raiſed with a certainty of their being the ſame, or not degenerating. It has been obſerved, that though the plants raiſed from ſeed are liable to run from their kinds, and afford ſuch fruits as are not worth the trouble of cultivation; thoſe procured from ſhoots taken from ſuch trees as produce good fruit, never alter from their kind, whatever the ſtock or tree on which they are grafted may be; as notwithſtanding the grafts receive their nouriſhment from the ſtocks, their varieties are never altered by them, but continue to produce the ſame kind of fruit as the tree from which they were taken: the only alteration which they undergo is, that when the ſtocks on which they are grafted do not grow ſo faſt, and afford a ſufficient ſupply of nouriſhment to the grafts, they do not make ſo great a progreſs as they otherwiſe would do, nor is the fruit they produce ſo fair, or ſometimes ſo well flavoured, or ſo large.

This proceſs has the advantage, probably from the ſupply of nutritious matter being not only more abundant but more regular, of rendering the plants or trees which are thus raiſed more quick in their arriving at the ſtate of maturity, or that of bearing.

It is on theſe different accounts that the practice of grafting is principally had recourſe to, in raiſing different ſorts of fruit trees, as well as ſome particular ſorts of ornamental plants of the tree and flower kinds. It alſo affords the means of growing different kinds of fruits and flowers of the ſame ſort, in the ſame ſtock or tree, as ſeveral varieties of pears and apples, &c.

There are different methods of performing this operation, and which are diſtinguiſhed by different terms or names, as below.

Rind, *Shoulder*, or *Crown Grafting*.—This is that mode in which the grafts are ſet in a ſort of circle or crown, upon the top of the cut-off ſtem or branch.

It is chiefly practiſed on large trees, when either the head or the large branches are cut off horizontally, and two or more ſhoots or ſcions put in, according to the ſize of the branch or ſtem: in performing which, the ſcions are cut flat on one ſide, with a ſhoulder to reſt upon the crown of the ſtock; then the rind of the ſtock is raiſed up, to admit them between the wood and the bark of the ſtock, which muſt be inſerted about two inches, ſo as that the ſhoulders may meet, and cloſely join the crown of the ſtock; and after the whole of the ſhoots or ſcions are inſerted, all the crown of the ſtock ſhould be well clayed over, leaving two eyes of them uncovered with it, which will be ſufficient for ſhooting. It is a method of grafting that was much more in practice formerly than at preſent, owing to the bad ſucceſs with which it has been attended; for, as the ſcions are placed between the rind of the ſtock and the wood, they are frequently blown out by ſtrong winds after they have made large ſhoots, ſometimes after five or ſix years growth. Where this method is practiſed, there ſhould therefore always be ſome ſtakes fixed, ſo as to ſupport the ſcions until they have almoſt covered the ſtock or branch. It is uſual to perform the operation in this mode of grafting about the beginning of April, or ſometimes a little later.

Stock, *Cleft*, or *Slit-Grafting*.—This is a mode which is practiſed upon ſtocks, trees, or branches, of a ſmaller ſize, as from one to two inches in diameter, and may be uſed with ſucceſs where the rind of the ſtock is not too thick, by which the inner bark of the ſcion will be prevented from joining to that of the ſtock. In performing it the head of the ſtock or branch muſt be cut off with a ſlope, and a ſlit be made the contrary way, in the top of the ſlope, deep enough to receive the ſcion, which ſhould be cut ſloping like a wedge, ſo as to fit the ſlit made in the ſtock; care being taken to leave that ſide of the wedge which is to be placed outward, much thicker than the other: and in putting the ſcion into the ſlit of the ſtock, great care muſt be taken to join the rind of the ſcion exactly to that of the ſtock; for if theſe do not unite perfectly, the grafts will not ſucceed: when this method of grafting is uſed to ſtocks that are not ſtrong, it will be proper to make a ligature of baſs, to prevent the ſlit of the ſtock from opening: after which the whole ſhould be clayed over, to prevent the air from penetrating the ſlit, ſo as to deſtroy the grafts, only leaving two eyes of the ſcion above the clay for ſhooting. It is uſually performed about the beginning of March, or ſometimes a little later.

Whip, or *Tongue-Grafting*.—This is moſt generally practiſed by nurſery-men, eſpecially for ſmall ſtocks, or branches of an inch, half an inch, or leſs, as the ſcions much ſooner cover the ſtocks in this method, than in the other. It is performed by cutting off the heads of the ſtocks ſloping; then making a notch in the ſlope towards the upper part downwards, a little more than half an inch deep, to receive the ſcion, which muſt be cut with the ſlope upward, and a ſlit made in this ſlope like a tongue, which tongue muſt be inſerted into the ſlit made in the ſlope of the ſtock, and the ſcion be placed on one ſide of the ſtock, ſo as that the two rinds of the ſcion and ſtock may be equal, and join together exactly; after which, there ſhould be a ligature of baſs put round to faſten the ſcion, ſo as that it may not be eaſily diſplaced, the whole being afterwards clayed over as in the former methods. It may be performed in the early ſpring months, with moſt ſucceſs.

There are, beſides theſe, ſome other modes of performing the buſineſs.

Grafting by Approach, or *Inarch-Grafting*.—This is ſometimes called ablactation. It is performed where the ſtocks that are deſigned to be grafted, and the trees from which the graft is to be taken, ſtand ſo near together, as that their branches may be bent and united. It is moſt commonly practiſed on tender exotic plants, and ſome other ſorts which do not ſucceed in any of the other methods. In performing the work, a part of the ſtock or branch is ſlit off about two inches in length, a ſmooth part of the ſtock being always choſen for the purpoſe; then a ſmall notch is made in this ſlit downward, in the ſame manner as directed for whip-grafting; the branch of the tree deſigned to be inarched having a part ſlit off in the ſame manner as the ſtock, and a ſlit made upward in it, ſo as to leave a tongue, which tongue ſhould be inſerted into the ſlit of the ſtock, joining their rinds equally, that they may unite well together; after which a ligature of baſs ſhould be made, ſo as to keep them exactly in their ſituation, and afterwards this part of the ſtock clayed over well to keep out the air. In this method of grafting, the ſcion is not ſeparated from the tree until it is firmly united with the ſtock, nor is the head of the ſtock or branch, which is grafted, cut off till the ſame time, and only half the wood pared off with a ſlope, about three inches in length, and the ſame of the ſcion or graft. But in this method of grafting, the operation is not performed ſo early in the ſeaſon as the others; it being done in the month of April, when the ſap is flowing, at which time the ſcion and ſtock will join together, and unite much ſooner than at any other ſeaſon or period of the year. It is principally employed in raiſing jaſmines, oranges, and other exotic trees of the harder kinds.

By experience it has been found, that the walnut, fig, and mulberry will take by this method of grafting, while neither of them ſucceed in any of the other modes. Several ſorts of evergreens may likewiſe be propagated by this method of grafting; but all the trees that are grafted in this way are weaker, and never grow to the ſize of thoſe which are grafted in the other methods; therefore it is rarely practiſed, except on ſuch ſorts of trees as will not take by the other methods of performing the operation.

Root-Grafting.—This, which is a late improved mode, is performed by cutting the clean ſmooth roots of the ſtocks in pieces of five or ſix inches long, and as large, or a little larger, than the graft; then they are whip-grafted, and tied together very cloſe, ſo as to prevent the wet from affecting the wounded parts, planting them ſo deep as that the graft, which ſhould be four or five inches long, may be about half buried. In this way, the grafts themſelves will root, and a nearer ſimilitude be preſerved to the tree, whence the grafts are taken; and after two or three years, the ſtock may be cut quite away, and the graft left to maintain itſelf. In practiſing this method, the grafts ſhould be an inch or two longer than the others.

Seaſon of Grafting.—The period or ſeaſon for grafting ſhould always be regulated by the ſtate of the weather. From the climate being ſo uncertain in the ſpring, it is beſt to defer it till the circulation of the ſap is briſk, and the buds of the ſtocks begin to break into leaves, attention being had that the weak ſhoots of tender trees will not admit of being ſo long cut as the more hardy, and that the operation ſhould never be performed while it actually freezes or rains, or there is ſnow upon the ground.

Proper Grafts.—In providing theſe, care ſhould be taken that they are ſhoots of the former year, as when they are older they never ſucceed well; that they be always taken from healthy fruitful trees, as when the trees are ſickly from whence they are taken, the grafts often partake ſo much of the diſtemper, as not to get the better of it, at leaſt for ſome years; that they be not taken from young luxuriant trees, whoſe veſſels are generally large, continuing to produce luxuriant ſhoots, and ſeldom proving fruitful; and that they be taken from the lateral or horizontal ſhoots, rather than the perpendicular ones. They ſhould be cut off from the trees before their buds begin to ſwell, which is moſtly three weeks or a month before the ſeaſon for grafting; conſequently when they are cut off, they ſhould be laid in the ground, with the cut part downwards, burying them half their length, and covering their tops with dry litter, to prevent their drying; if a ſmall joint of the former year's wood be cut off with the ſcion, it will preſerve it the better, and when they are grafted, this may be cut off; for, at the ſame time, the ſcions muſt be cut to a proper length before they are inſerted in the ſtocks; but, till then, the ſhoots ſhould remain of their full length, as they were taken from the tree, which will better preſerve them from ſhrinking: when the ſcions are to be carried to a conſiderable diſtance, it will be proper to put their ends into a lump of clay, and to wrap them up in moſs, which will preſerve them freſh for a month or longer: but theſe ſhould be cut off from the trees earlier than thoſe which are to be grafted near the place where the trees are growing. It is, however, always the beſt practice to cut the grafts as near the time of their being inſerted into the ſtocks as poſſible, as by that means they ſucceed with much more certainty.

Stocks proper for Grafting upon.—The ſtocks are the trees or plants for grafting upon; which are either ſuch old trees as are already growing where they are to remain, but the fruit of which is intended to be changed; or ſuch young trees as have been raiſed in the nurſery as a ſupply to the garden. In the former caſe, there is no other choice than that of the branches, which ſhould be ſuch as are young, healthy, well-ſituated, and have a ſmooth bark. Where theſe trees are growing againſt walls or eſpaliers, it will be proper to graft ſix, eight, or ten branches, according to the ſize of the tree, by which they will be much ſooner furniſhed with branches again, than when a leſs number of ſhoots or ſcions are put in; but in ſtandard trees, four, or at moſt ſix ſcions will be ſufficient for the purpoſe.

In chooſing young ſtocks for grafting upon, ſuch as have been raiſed from the ſeed, and that have been once or twice tranſplanted, ſhould always be fixed upon for the purpoſe.

After theſe, thoſe ſtocks which have been raiſed from cuttings or layers ſhould conſtantly be preferred; but thoſe which are ſuckers from the roots of other trees ſhould be rejected, as they are never ſo well rooted as the others, and conſtantly put out a great number of ſuckers from the roots, by which the borders and walks of the garden will be always peſtered during the ſummer ſeaſon. Theſe, beſides being unſightly, take off part of the nouriſhment from the other trees and plants.

And where theſe ſtocks have been allowed a proper diſtance in the nurſery where they have grown, the wood will be better ripened and more compact than thoſe which have grown cloſe, and have been drawn up to a greater height. The wood of theſe will be ſoft, and their veſſels large; ſo that the ſcions grafted into them will ſhoot very ſtrong; but they will be leſs diſpoſed to produce fruit than the others; and when trees acquire a bad habit at firſt, it is difficult to reclaim them afterwards. The ſtocks moſt adapted to each ſort will be explained under their particular genera, and in conſidering the nature of ſtocks. See STOCKS.

Implements proper for the Work.—Theſe are principally a neat ſmall hand-ſaw, for cutting off the heads of large ſtocks; a good ſtrong knife, with a thick back, to make clefts in the ſtocks; with a ſharp pen-knife, or budding-knife, to cut the grafts with; and a grafting chiſſel and ſmall mallet. Other ſorts of implements are ſometimes neceſſary in performing particular ſorts of grafting.

But beſides theſe tools, other ſorts of materials are wanted in performing the buſineſs, ſuch as baſs-ſtrings, or woollen yarn, to tie the grafts with; and a quantity of good tough clay, which ſhould be prepared a month before it is wanted, and kept turned and mixed, like mortar, every other day, in the following manner:

A quantity of ſtrong good clay, in proportion to the quantity of trees intended to be grafted, ſhould be provided, and ſome new well-fed horſe-dung broken in among it; and if a little ſtraw or hay be mixed amongſt it, it will hold together the better. The addition of a quantity of ſalt will alſo prevent the clay from dividing in dry weather. Theſe ſhould be ſtirred and mixed together, putting water to them occaſionally, in the manner of making mortar. The whole ſhould be hollowed like a diſh, filled with water, and kept every other day ſtirred. It ſhould be carefully kept from being expoſed to froſt or drying winds; and the oftener it is wrought over the better it will become.

Some have lately made uſe of another ſort of compoſition for grafting, which has been found to anſwer the intention of keeping out the air better than the clayey mixture. It is compoſed of turpentine, bees'-wax, and roſin melted together; which, when of a proper conſiſtence, is put on the ſtock round the graft, in the ſame manner as the clay is uſually applied; and though it be not above a quarter of an inch thick, it keeps out the air more effectually than the clay; and, as cold hardens it, there is no danger of its being hurt by froſt, which is very apt to cauſe the clay to crack, and fall off; and, when the heat of the ſummer comes on, it melts and falls off without any trouble. In the uſing it, a tin or copper pot is neceſſary, with a convenience under it to keep a very gentle fire with ſmall coal; otherwiſe the cold ſoon condenſes the mixture. It is neceſſary not to apply it too hot, leſt the graft be injured. A perſon a little accuſtomed to this compoſition, applies it very faſt; and it is much eaſier for him to work with than clay, eſpecially when the ſeaſon proves cold.

In the buſineſs of grafting it is found, that in long-continued dry ſeaſons the grafts are liable to fail in taking, which is ſometimes probably owing to the improper choice of the grafts, as well as to the dry weather. Great care ſhould of courſe always be taken not to graft with weak ſhoots, particularly thoſe taken from near the top, but ſuch as are taken from the lower end of the ſhoots, and in which the wood is plump and freſh: ſuch as are ſhrivelled ſeldom or ever take well. When any have miſſed in the ſpring, it has been adviſed to cut off, about the middle or latter end of June, ſome fine, healthy grafts of the ſorts that are wiſhed to graft with, and to open the bark in the ſame manner as for budding, inſerting the graft with a piece of the former year's wood on it, and after this has been done, to rub in with a bruſh ſome of the compoſition of Mr. Forſyth in a liquid ſtate; then to warp baſs round it, as is done for ſpring grafting, leaving about three eyes in the ſhoot, which ſhould be tied on with the baſs as light as poſſible; then covering the outſide of the baſs, thus tied up, with the compoſition to the thickneſs of about one-eighth of an inch, as well as the end of the ſhoot, to exclude the air and wet. In about three weeks or a month, the grafts ſhould be looked over, to ſee if they have taken. When the graft begins to ſwell, it will throw off the compoſition; in which caſe always remember to apply more to prevent the air from penetrating the inciſion or wound that has been formed.

About the month of September it ſhould be examined whether the wounds are all healed up, and the two barks perfectly united; which, if they are, ſlacken the baſs; and when they are perfectly healed up, it may be wholly taken off; but if not, the baſs muſt be again tied on, and covered with a compoſition as before, letting it remain till the following ſpring. It may then be taken off; and if it be found that the two barks have ſeparated during the winter, with the point of a ſharp knife, all the brown part of the bark (which, if left, would infallibly bring on the canker) ſhould be cut out, and the compoſition rubbed into the wound. When the grafts have produced ſtrong leading ſhoots, the tops of them ſhould be pinched off with the finger and thumb; but if they have not ſhot ſtrong, they ſhould not be cut till the ſpring, when they may be cut down to three or four eyes, according to their ſtrength, to make them produce horizontal ſhoots, and form handſome heads. This ſort of grafting ſhould always be performed in moiſt or cloudy weather, if poſſible, as under ſuch circumſtances the operation moſtly ſucceeds better.

It has been remarked by Mr. Forſyth, that rubbing a little of his compoſition into the inciſion will effectually prevent the canker, and in applying it round the graft, a much leſs quantity is ſufficient than of the clay; as it need not be more than three inches round in grafting ſmall ſtems or ſhoots, and in proportion for thoſe which are larger. It keeps the ſcion moiſt. When uſed in grafting, it ſhould be of ſuch a conſiſtence as to work eaſily with the hand, or a knife, or ſmall trowel, rather ſofter than grafting-clay generally is. This method, on a fair trial, will, he thinks, be found "a ſure, neat, and expeditious way of grafting."

In grafting, or budding, they ſhould be performed as near to the upper ſide of a bud as poſſible, and the moſt proper place for inſerting the ſcions or buds is at the joints, a little above the croſs ſhoot.

And in reſpect to the ſorts of trees that will ſucceed upon one another, it may be obſerved that all ſuch as are of the ſame genus, that is, which agree in their flower and fruit, take upon each other; hence all the nut-bearing trees may be ſafely grafted on each other, as well as all the plum-bearing trees, as the ſeveral ſorts of plums, almond, peach, nectarine, apricot, &c.; but as many of them are ſubject to admit gum from the parts wounded, as the peach and nectarine kinds, it is found the ſureſt method to bud or inoculate them.

All ſuch trees as bear cones alſo do well upon each other, though they may differ in one being evergreen, and the other ſhedding its leaves in winter; as in the cedar of Libanus, and the larch-tree, which are found to ſucceed upon each other; but they muſt be grafted by approach, as they abound with a great quantity of reſin, which is apt to evaporate from the graft, when ſeparated from the tree before it is joined with the ſtock; whereby they are often deſtroyed. The laurel likewiſe on the cherry, or the cherry on the laurel. All the maſt-bearing trees are alſo found to take upon each other, and thoſe which have a tender ſoft wood do well if grafted in the common way; but ſuch as are of a firm contexture, and are ſlow growers, muſt be grafted by approach.

It is likewiſe by this method that many kinds of exotic trees are not only propagated, but alſo rendered hardy enough to endure the cold of our climate in the open air; as by being grafted upon ſtocks of the ſame kind which are hardy, the grafts are rendered more capable of enduring the cold, and the general effects of the atmoſphere.

GRAFTING *Wax*. See WAX.

GRAFTING *Tool*, in *Engineery*, ſignifies a kind of ſpade, made very ſtrong and curving, uſed in digging canals, often called only a *tool*; ſee *fig*. 50. CANALS, *Plate* VII.

GRAFTON, in *Geography*, a town of America, in Windham county, Vermont, chartered by the name of Tomlinſon, but aſſuming its new name in 1791. It contains 1149 inhabitants, and lies W. of Rockingham, adjoining.

GRAFTON *County*, a county of New Hampſhire, bounded N. by Canada, S. by the counties of Strafford, Hillſborough, and Cheſhire, W. by the ſtate of Virginia, and E. by the diſtrict of Maine. It is divided into 50 townſhips, and 17 locations, and contains 23,093 inhabitants.

GRAFTON, a poſt-town in the county above-mentioned, 13 miles S.E. of Dartmouth college, and 19 S.W. of Plymouth. It was incorporated in 1778, and contains 682 inhabitants. Lapis ſpecularis, of the beſt quality, is found in this town; it lies in a mountain about 20 miles E. of Dartmouth college, adhering to the rocks of white or yellow quartz, and lying in laminæ, like ſheets of paper.

GRAFTON, the *Hoſſanamiſco* of the Indians, a townſhip in Worceſter county, Maſſachuſetts, containing 985 inhabitants; 40 miles S.W. of Boſton.

GRAFTON, *Cape*, a cape on the coaſt of New Holland, ſo called by Cook in 1770. S. lat. 16° 57′. W. long. 214° 6′.

Grafton *Iſland*, the moſt northerly of the Baſhee iſlands, in the Eaſt Indian ſea. N. lat. 21° 8′. E. long 118° 14′.

GRAGNANO, a town of Naples, in Principato Citra; 11 miles W.S.W. of Salerno.

GRAHAM's Island, one of the Aladin iſlands, in the Mergui Archipelago, about 6 miles in circumference. N. lat. 9° 19′.

GRAIG, or Graignamanna, a poſt-town of Ireland, in the county of Kilkenny. Here is a good bridge over the Barrow, and the tide flows up. It is 58 miles S. by W. from Dublin.

GRAIN, John Baptist le, in *Biography*, was born, in 1565, at Paris, where he was educated with great care, and in early youth he was introduced to court, and attached himſelf to the ſervice of Henry IV. He was appointed by that prince to the office of counſellor, and maſter of requeſts in ordinary to the queen, Mary de Medicis. His employment was in writing, and in attending on the education of his children. On their account he drew up Memoirs relative to the hiſtory of France, which remained in MS. till the chancellor de Sillery perſuaded him to publiſh a part of them. His firſt publication, which he printed in his own houſe, was entitled, "Decade contenant l'Hiſtoire de Henri le Grand, Roi de France et Navarre, IV. du Nom." fol. 1614, in ten books. It comprizes the period from the peace in 1559, to the king's death in 1610. He publiſhed a ſecond decade, including the hiſtory of that king's reign, in 1618. The former decade was preſented to the young king Lewis XIII. who was highly delighted with the freedom diſplayed by the author, and it was at his deſire that the other was made public. Le Grain, though fortunate in pleaſing his ſovereign, made himſelf many enemies by the honeſty and candour which he diſplayed in the narration. Attempts were made to procure a cenſure upon it from the Sorbonne, but they were unſucceſsful, that body declaring that they found nothing in it deſerving of cenſure. The real grounds of the objections to it were that the author had ſupported the liberties of the Gallican church; that he had cenſured attempts to introduce into France thoſe articles of the council of Trent, which had been rejected; – that he diſapproved the eſtabliſhment of new religious orders, and was not favourable to the perſecution of heretics. For theſe ſentiments, which ought to have endeared him to his countrymen, he was continually haraſſed by bigots, till at length an order was procured from the king for the ſuppreſſion of all the copies of his work, which remained in his hands. The treatment which he experienced diſguſted him with the court, and he went into retirement on his eſtate of Montgeron, where he died in 1642. He left in MS. a manifeſto relating to all the proceedings reſpecting his book, which is ſaid to diſplay in glowing colours the diſcouragements attending honeſt hiſtorians under an abſolute monarchy. He left likewiſe the third decade of his hiſtory, and ſome chronological pieces in MS. Moreri.

GRAIN, Granum, primarily denotes a fruit, or ſeed, growing in a ſpica, or ear.

In this ſenſe, grain comprehends all ſorts of corn; as wheat, rye, barley, oats, &c.

Grain, *Structure of.* There are three particulars obſervable in every grain, whether it be wheat, barley, oat, or whatever elſe of that kind. Theſe are, 1. The outer coat or pellicle, which contains all the reſt. This in the ſame ſpecies of grain is found to be very different in thickneſs in different ears, and as it has grown in different ſoils, 2 The germ or bud; this is always hid within the ſeed or grain, and is the plant in miniature that is to ariſe from it. (See Bud and Germ.) And, 3. The meal, or that farinaceous matter which is incloſed in the ſkin, and which ſurrounds the germ, and ſerves to give it nouriſhment when firſt put into the earth, before it is capable of drawing it from the earth itſelf. Dr. Grew, in his Anatomy of Plants, has treated of this at large. See Fecundation *of Plants*, Germination, Vegetation, &c.

The whole ſtructure of the plant which produces theſe ſeeds is equally admirable. The chaffy huſk is admirably adapted to ſhield and defend the ſeed as long as that is neceſſary, and then to let it fall; and the ſtalk, formed hollow and round, is neceſſarily at once light and ſtrong, capable of ſuſtaining the ear, without abſorbing too much of the juices deſtined to its nouriſhment; and the beards of many kinds are a defence againſt the birds, that would otherwiſe deſtroy the ſeed before its ripening. The covering of the ſeed is formed of two membranes, which meeting in a line on one part of the ſeed, form together that furrow we ſee on it. This is the place at which the ſeed is to burſt open on being moiſtened. Had not nature provided this means of the germ's coming out, the toughneſs neceſſary to the coat of the ſeed, as a defence from injuries, would have ſuffered the farinaceous matter and the germ to rot together, within it, before it would have given them way to come out, and for the germ to grow.

Nor is this the only uſe of this place of opening. The great Creator of all things has provided theſe ſeeds, not only for a ſupply of the ſame ſpecies of plant, but for our food, and for that of birds, &c. We have art enough to erect machines for the reducing of the farina to powder, and the freeing of it from its covering membrane; but the birds eat it as it is, and it would paſs through them whole, and without doing them any good, were it not that the juices of the ſtomach ſwelling it up, it burſts open at this furrow, and all the nutritive matter pours itſelf out. De Landes, Trait. Phyſ. p. 62. See Farina, Fecula, Flour, Bread, &c.

For the laws relating to the importation and exportation of ſeveral ſorts of grain, as wheat, barley, oats, &c. See Corn.

The cleaning and preſerving of grain in a proper ſweet condition have long been objects of conſiderable importance, but it is probable that the latter cannot be effected for any great length of time.

Different methods of managing grain, after being threſhed out, are practiſed by farmers; ſome keeping a large proportion of it in the chaff on the barn floors, while others, after having it cleaned, put it into ſacks, and place them in the ſame ſituation, or in ſome room appropriated to the purpoſe, until they can be ſent to the market. But each of theſe methods is liable to much objection; as when it remains for any length of time on low damp floors, it muſt obviouſly ſoon become muſty, however much precaution is taken to prevent it, whether it be in ſacks, or in a looſe ſtate without being cleaned.

There is another practice ſometimes employed in the more northern parts of Scotland, according to the author of "Modern Agriculture;" which is, that of twiſting ſtraw into large bands, or ropes, and coiling them up in the manner of the cables of ſhips, placing the grain, when threſhed and cleaned, within the coils, in a ſort of well, as it were. But as the grain in this way reſts on the ground or floor, and, of courſe, is liable to imbibe damp, it is not leſs objectionable than the others, while it is much more troubleſome, and more expoſed to loſs.

It has been adviſed, in order to preſerve grain in a proper ſtate after threſhing it out, to have it as expeditiouſly as poſſible cleaned from the chaff, when the air is in a dry ſtate, and put into a room, cheſt, or bin, which is perfectly dry and free from any ſort of moiſture, until it can be properly placed in the granary, or be ſent away for ſale. This ſhould always be effected as early as poſſible, as, by delaying the cleaning of the corn, the ſample is very liable to be injured.

The cleaning of the grain is performed in ſeveral different ways; but where threſhing-machines are in uſe, they are now moſtly contrived in ſuch a way as to execute it at the ſame time the threſhing is going on. The winnowing-machine is alſo frequently employed for the ſame purpoſe, and anſwers perfectly well. And in ſome ſituations the *caſting-ſhovel* and *ſpry*, or flat broom, as well as the *ſcuttle*, are made uſe of, the broom ſerving to remove the chaffy parts and the more minute ſtrawy particles which are ſeparated from the grain by the wind. This method can, however, only be employed with advantage where there is plenty of barn-room; under other circumſtances the winnowing-machine is far more beneficial and proper. The practice of cleaning grain on the barn-floor, by means of the wind, is not only tedious and troubleſome, but an extremely imperfect method.

In whatever way the extraneous matters have been removed from grain, it ſhould, as ſoon as the operation has been performed, eſpecially in barley and wheat, be put through a ſcreen-machine, which, in moſt of the more improved threſhing and winnowing-machines, is provided with this intention, and is thereby rendered free from all ſorts of ſmall ſeeds and other foreign matters. In this way the ova of different ſorts of inſects are alſo removed, and the production of the weevil, moth, beetle, &c. prevented, as well as the deſtruction which they commit while in their vermicular ſtate, guarded againſt.

Screen machines may be had ſeparately from the others; but the work of cleaning the grain is the moſt readily, cheaply, and conveniently performed, where they are connected with the other neceſſary machinery.

It has been ſuggeſted, that as the prevention of all ſorts of corn from being affected by the different cauſes that have a tendency to injure it, when laid up for the purpoſe of keeping, depends upon its being put by in a perfectly dry condition, and on its being afterwards preſerved in that ſituation; it is of much conſequence, in theſe views, to keep it, from the period of its being threſhed out of the ſtraw, as much as poſſible from coming in contact with the earth, ſtone, or any other ſorts of floors that are placed near to, or upon the ground, as they have conſtantly a great diſpoſition to communicate moiſture, and in that way injure the grain that reſts upon them.

It is likewiſe found to be a highly beneficial practice to prevent, as much as poſſible, the entrance of the atmoſpheric air, whenever it is much loaded with humidity; as from the vaſt extent of ſurface that is expoſed to its action, it is eaſy to perceive that it muſt be highly prejudicial to the corn, by imparting its moiſture to it, as a ſort of mucor, or mouldineſs, is thereby brought on, that is attended with a muſty diſguſting ſmell, and that prevents its keeping in a proper manner. In regard to the means of prevention, they muſt be different in different caſes; but much may be done in the firſt of the above ſituations, by cautiouſly avoiding the too general practices of permitting the corn to remain upon the threſhing-floors in the barns, particularly where they are of the earthy or ſtoney kinds, too long after it is threſhed out, before it is cleaned from the chaff, and other uſeleſs matters: or, after it has been cleaned, by preventing its being depoſited upon them, either in the looſe ſtate, or in ſacks. And farther, by having great regard to the dryneſs of the air when the buſineſs is performed.

In inſtances of the latter kind much is capable of being accompliſhed by having proper apparatus, ſuch as ſlides, ſhutters, and other ſuitable contrivances, fixed in the pipes, funnels, and other openings, deſigned for the purpoſe of ventilation in the corn-chambers and granaries; which ſhould be preſerved, conſtantly ſhut in a cloſe manner at all times when the air is much impregnated with watery particles, ſo as to prove hurtful to the grain. Damp and froſty weather are, of courſe, always improper for expoſing grain to the air in, as it muſt, in ſuch ſeaſons, do great miſchief. But, beſides air, light is eſſential in the preſervation of grain in theſe circumſtances, as, where it is not admitted pretty freely, a kind of vegetable mucor, or mould, as already noticed, is liable to fix upon the grain, and injure it greatly. The ingenious author of the "Philoſophy of Gardening and Agriculture," has remarked, that this poſſeſſes the ſame property as that of other funguſes, of growing where there is ſcarcely any change of air, and in places where there is little or no light, provided there be the neceſſary degree of warmth and moiſture. On the ſame principle, with the intention of retaining the grain in a ſtate as free as poſſible from dampneſs, it is ſuggeſted by the ſame writer, that it might be uſeful to have well conſtructed ſtoves in the bottom parts of corn-chambers and granaries, for the purpoſe of occaſionally communicating ſuch moderate degrees of heat to the grain as would be ſufficient to dry up and expel any injurious moiſture that it might have attracted in damp wet ſeaſons. On this idea it has, indeed, long ago been recommended as ſupported by experience by Mr. Tull, to preſerve wheat, by expoſing it to the action of a ſun-ſhine degree of heat upon a hair-cloth, in a malt-kiln, produced by the combuſtion of clean ſtraw, for ſuch a length of time as may be neceſſary to remove the dampneſs, as from four or five to ten or twelve hours, according to the proportion in which it may exiſt. But in this method the heat ſhould be conſtantly kept ſo moderate as not to deſtroy the vegetative property, or life of the grain, as, if that were the caſe, its putrefaction and decay would be promoted. The degrees of heat that would be the moſt adapted to anſwer the purpoſe, in different caſes, would be eaſily regulated by thoſe inſtruments which are in general uſe for meaſuring the heat and moiſture of the atmoſphere. Theſe principles aſſiſt us much in reconciling the differences of opinion that have ſo long prevailed in reſpect to the uſe of air in the preſervation of corn in granaries, as they ſufficiently ſhow, that when admitted in its perfectly dry and elaſtic ſtate, it muſt be particularly uſeful in carrying off any moiſture or diſagreeable ſmell that the grain may have contracted by remaining cloſely heaped together for ſome length of time; as, by the ſtirring that moſtly accompanies the ventilation, it muſt neceſſarily operate in a very extenſive manner; but that when applied in its moiſt heavy ſtate, it muſt be detrimental in an equally proportionate degree, by imparting its humidity to the grain, and thereby cauſing a ſort of muſtineſs.

It is probable that the ventilation of grain is the moſt completely effected by ſtirring it by means of proper ſlides, doors, or other ſimilar contrivances made in the floors, windows, and other openings of the granaries or corn-chambers; but it is capable of being accompliſhed in a more ſlow and leſs economical manner by ſhovels, rakes, and other ſimilar tools. And in order that the work may be more readily and more effectually performed, the grain ſhould not be ſpread out too thickly over the floors of the granaries and corn-rooms. From one to two feet, or two feet and a half in depth, is conſidered fully ſufficient for the purpoſe, in proportion as it becomes more dry and the moiſture more diſſipated. When grain is heaped together to too great a thickneſs at firſt, from the natural moiſture which it contains, it is frequently apt to heat, and thereby greatly injure the ſample. Frequent ſcreening ſhould likewiſe be had recourſe to immediately after its being depoſited in the corn-rooms, and occaſionally at other times as circumſtances may demand.

Other points have been ſuggeſted by Doctor Darwin, as neceſſary to be attended to in this buſineſs, in order to perform it in the moſt effectual manner; ſuch as thoſe of having the doors, windows, and other principal apertures of the buildings placed in ſuch a manner as to face the ſouth, and as cloſe to the ceiling as poſſible, ſo that the rays of the ſun may enter with the greateſt freedom. And in addition, the linings of all ſuch corn-rooms ſhould conſtantly be formed of ſuch materials, as have no tendency from their coldneſs to precipitate the moiſture from the atmoſphere, which is frequently the caſe with particular ſubſtances, when warm, damp, ſouth-weſt winds take place after cold or eaſt ones, and in that way impart it to the grain that comes in contact with them. It is alſo equally neceſſary in all ſuch caſes that the entrance of wet and moiſture ſhould be prevented in an effectual manner, by having recourſe to proper ſheltering boards, ſlides, and other contrivances of the ſame kind.

There is likewiſe a particular ſort of management neceſſary in the turning over and ſtirring of grain in order to its complete ventilation, as when the corn is firſt placed in the rooms it ſtands in need of much more frequent turning over than afterwards, when it has parted with a conſiderable proportion of its moiſture and is become ſomewhat dry. For the firſt month or ſix weeks, once or twice in every week or ten days may be ſufficient to anſwer the purpoſe; but afterwards for four or five months longer, about once in the fortnight may commonly be ſufficient, and from that period only once in the month, except when the ſeaſon proves very moiſt, warm, and of courſe improper for keeping the grain well.

In order to accompliſh this buſineſs different methods are in uſe; it is the cuſtom in ſome places to have empty ſpaces left on the ſides of the heaps of grain and other parts into which they may be turned over when neceſſary; while in others, ſquare holes are formed in the ends of the floors, and round ones in the middle, by which means the grain is thrown from the upper to the lower chambers, and back again, and of courſe becomes agitated and expoſed to the air in a more perfect manner. This is a method that is practiſed with ſucceſs in ſome parts of the county of Kent. As, however, in theſe modes ſuch frequent turnings are not only extremely troubleſome, but expenſive, in conſequence, eſpecially in the firſt caſe, of being performed by the ſhovel, the plan of having ſliding ſhutters in the middle of the different floors ſo contrived, as to have an inclination towards the centre of the granaries, has been had recourſe to; by the occaſional removal of which, and the opening of the windows and ventilators, the grain is turned and expoſed to the influence of the air at the ſame time with great eaſe, convenience, and diſpatch.

This mode of preſerving grain was long ago found by Monſieur du Hamel to anſwer perfectly well, even in caſes where it had been laid up in a moiſt, damp, and improper ſtate.

There can be no doubt, however, but that grain may be preſerved without having recourſe to the means of ventilation, by depoſiting it, when in a perfectly dry ſtate, in deep wells, pits, and caverns that are free from any ſort of damp and moiſture, and ſo far below the ſurface of the ground that it cannot be affected by the heat or the changes that take place in the ſeaſons. But though grain has been known to have been preſerved in this manner for a great length of time in thoſe countries where it is the practice to have it ſtored up for times of ſcarcity, it is by no means either a very ſafe or convenient method.

It muſt be obſerved, however, that in whatever manner grain is ſecured, it is eſſentially neceſſary that care ſhould be taken that ſuch portions as are in a ſoft damp ſtate, or which have been badly harveſted, ſhould not, on any account be laid up with that which is in a dry condition and perfectly ſound; as from the quantity of moiſture that is contained in it, and the tendency to germination that takes place in conſequence of it, a muſty bad ſmell is liable to be imparted to the whole, and the ſample either totally or in a great degree deſtroyed.

The practice of expoſing grain to the free action of the atmoſpheric air, has been diſcarded by ſome in conſequence of the ova or eggs of inſects being liable in that way to be depoſited among the grain, but it would ſeem more probable, when the economy of ſuch inſects is well conſidered, that their ova were either depoſited originally among the grain in ſuch ſituations, or brought in with different parcels of it from different places. On this account it is evident that great caution ſhould be uſed in furniſhing freſh parcels of grain for being laid up, and that the ſcreen ſhould be conſtantly employed before putting it into the rooms.

It is, however, pretty certain that where grain is to be preſerved for much length of time, though it may without doubt be ſafely kept in the ways that have been already mentioned; yet it is moſt probably not only a much better, but more certain and economical method to let it remain unthreſhed from the ear in the ſtacks in which it has been built, particularly where they reſt upon ſtaddles that are properly conſtructed for the purpoſe.

It may be proper to obſerve, that where grain is to be long preſerved after being threſhed out, there ſhould always be proper buildings of the granary kind provided for its reception, the ſizes of which ſhould be proportioned to the extent of the farm, being conſtantly adequate to contain about one-half of the grain-produce after it has been threſhed out and cleaned.

In caſes where the grain is ground and preſerved afterwards in the ſtate of meal, it is the uſual and by far the beſt mode to pack it very cloſely by means of treading or ramming it into dry, cloſe, ſmall rooms, or large cheſts, as, in this way, when laid up in a proper condition, it will keep for a very great length of time quite ſafe and free from miſchief.

But, notwithſtanding the cuſtom of preſerving grain in ſtacks and granaries, from the convenience of it, may, in ſome inſtances, be beneficial, not only to the farmer, but the public, and, conſequently, in ſome meaſure neceſſary, it is clear from the trials that have been already made, that the ſtoring of grain in either way ſhould be carried to as ſmall an extent as poſſible, as it has been aſcertained that there is a conſtant decreaſe taking place in its weight from the period at which it has been harveſted or laid up, but that this loſs is far greater at firſt, than after it has been kept ſome time.

In the ſecond volume of the new edition of Georgical

Eſſays, publiſhed by Doctor Hunter, the loſs is ſtated by Mr. Holt to be in the following proportions in different ſorts of grain :

In Wheat.

	lb.	*oz.*	*drs.*
On being rubbed out in the hot-ſun, and weighed the 31ſt of Auguſt, 1789, ſoon after being cut, afforded	0	2	11
On being weighed again on the 18th of October	0	2	7
Loſs of weight, *per* buſhel, of 70lbs. nearly	6	8	3
Or almoſt one-tenth of the whole in forty days.			
Of this wheat, thirty-two grains weighed one penny-weight.			

It is, however, remarked, that this is the greateſt poſſible loſs that the grain can ſuſtain, as though it was in a full ſtate of maturity or ripeneſs, it had neither had the benefit of being dried by expoſure to the ſun after being cut, nor undergone the proceſs of fermentation after it was put together.

In Wheat.

	lb.	*oz.*	*drs.*
Another quantity, weighed on the 22d of October, produced	0	6	3
Weighed again 24 days afterwards, afforded	0	6	0
Loſs in that time *per* buſhel, at the rate of	2	11	15
A further quantity, weighed on the 8th of January, 1790, produced	0	2	2
Loſs *per* buſhel, on being weighed again 32 days afterwards, at the rate of	2	0	15

In Barley.

On being weighed on the 2d of September, under ſimilar circumſtances, produced	0	2	2
On being weighed again on October the 18th, afforded	0	1	12
Loſs of weight *per* buſhel of 60 lbs.	8	4	22
Or about one-ſeventh of the whole in 47 days.			
Twenty-four grains of this barley were found to weigh one penny-weight two grains.			

In Oats.

With this ſort of grain no experiment appears to have been made by the writer, but there can be no doubt but that the loſs muſt be equally great as in any of the other ſorts.

The reſults of theſe trials render it ſufficiently evident, that the more expeditiouſly grain is brought to the market, the leſs is the loſs which is ſuſtained by the cultivator. Of courſe it ſhould never be laid up or kept in any other way longer than circumſtances render it neceſſary. But in addition to the loſs that has been ſeen to occur from the gradual diminution in the weight of the grain in conſequence of the diſſipation of the more moiſt particles which it contains, there are others that ariſe occaſionally from the ravages of different kinds of vermin, and the effects of damps, muſtineſs, and ſeveral other cauſes.

In regard to the preſervation of grain from the depredations of inſects, and other ſimilar animals, it may probably be the beſt accompliſhed by a timely and frequent uſe of the ſcreen, with proper ventilation, as has been noticed above. Where the injury is produced by the weevil, the moth, or the beetle, it has always ceaſed at the period when theſe vermin appear, as they are, when in this ſtate of exiſtence, merely propagators of their ſeveral reſpective kinds of vermiculi, which, while they continued in that ſtate or form, produced the injury.

In their ultimate or inſect ſtate they eat or conſume very little, their buſineſs being principally that of depoſiting their ova or eggs, which they do by a ſort of unerring inſtinct, in ſituations where the large collections of grain are ſure to furniſh food for their ſucceſſors during the period in which they are in the vermicular ſtate. It is conſequently a matter of great moment to prevent the generation of them, by the deſtruction of the eggs before they are hatched, which is uſually the beſt performed by having recourſe to the ſcreen, and expoſure to a free air, as has been already ſhewn. The frequent ſtirring of the grain breaks the coheſion of their ova, by which the nidus of ſuch minute vermiculi is deſtroyed, as on hatching they collect together, and ſpin or weave numerous neſts of a cob-web-like ſubſtance for their own ſecurity and protection. And a great number of grains are attached together by them to theſe neſts, by an infinity of ſmall threads, both for their ſafety and food. Conſequently, when their habitations are broken and ſeparated by the uſe of the ſcreen, they fall through its ſmall interſtices, and are capable of being eaſily removed with the duſt and other refuſe matters: and ſuch as eſcape the early ſcreenings are deſtroyed by thoſe that follow, and the grain of courſe little injured by the operation, being only rendered more clean and free from impurities. See HARVESTING *of Grain*, REAPING *of Grain*, and STACKING *of Grain*.

GRAIN is alſo applied to the fruits or ſeeds of divers plants, as a grain of millet, of pepper, &c.

GRAIN is alſo extended to a minute body, or parcel of a body pulverized. In which ſenſe we ſay, a grain of ſand, a grain of ſalt, a grain of gunpowder, &c.

GRAIN denotes alſo a ſmall weight, uſed in eſtimating divers ſubſtances.

The grain is the ſmalleſt of all weights known in England. It is taken from the weight of a grain of wheat, gathered out of the middle of the ear, and well dried. By ſtat. 12 Henry VII. cap 7. every ſterling or penny-weight was to weigh thirty-two ſuch grains; but now twenty-four grains make a penny-weight, and twenty penny-weights an ounce. See PENNY and WEIGHT.

The grain is troy weight, and uſed in the weighing of gold, ſilver, jewels, bread, and liquors.

Among the ancients, the grain was the fourth part of the ſiliqua, or twelfth of the obolus, and the twenty-ſecond of the drachma. It coincided with lens.

Fernelius, lib. iv. cap. 6. Method. Medend. affirms it as a thing known and certain, that the grain is of the ſame weight every where: but he is miſtaken. Mr. Greaves, in his treatiſe of the Denarius, in his Miſcell. Works, vol. i. p. 276. has ſhewn, that 179 Dutch grains, which Snellius had found to be the weight of a Philip of gold, only amount to 134½ Engliſh grains. Add, that Monſ. Perrault has computed the French grain to be leſs than the Engliſh, and yet bigger than the Dutch; to the Engliſh, it is as 158 to 134½; and to that of Holland, as 158 to 179. See WEIGHT.

The grain uſed by the apothecaries is the ſame with that of the goldſmiths; though they make a difference in the weights raiſed from it. Thus, 20 grains, with them, make a ſcruple, ℈; 3 ſcruples, a drachm, ʒ; 8 drachms, an ounce, ℥, &c.

The carat uſed in eſtimating the fineneſs of gold, as well as in weighing diamonds and precious ſtones, is alſo divided into four grains; and the carat is about the one hundredth and fiftieth part of an ounce troy, according to Mr. Jeffreys, in his treatiſe on Diamonds and Pearls.

Hence, the jewellers' grain is to the troy grain, inverſely, as 600 is to 480, that is, directly as four to five.

Grain, in Engliſh troy and apothecaries weight, is the 480th part of a troy pound = 20 mites = 480 droits = 9600 periots = 230400 blacks, of the aſſayiſts, = .820386 French grains = .06475 grammes of the new weights of France = .000142857 pounds avoirdupoiſe.

Grain, a weight in France, = 1.21893 Engliſh troy grains = .00017413 Engliſh pounds avoirdupoiſe = .0531217 grammes of the new weights.

Grain is alſo uſed for the figure or repreſentation of grains on ſtones, ſtuffs, leathers, &c. Thus we ſay, morocco has a bolder and richer, that is, a larger grain, than ſhagreen.

In ſome marbles, the grain is very fine; in others coarſer. Steel is known by its grain, which is much finer than that of iron.

Grain, in *Mining*, is applied by quarry-men and maſons to the minute figures in moſt blocks of ſtone, by which they are diſpoſed to ſplit moſt eaſily in ſome certain direction, than in any other, as wood is diſpoſed to ſplit in the direction of its grain. Beat, ſheet, lamella, and ſtratula, are other terms of almoſt ſimilar import. Experienced maſons can generally diſcover the grain of the moſt homogeneous or perfect free-ſtone blocks, or ſuch as will cut with equal eaſe in any direction, and this they often do, by obſerving the directions of the very minute plates of mica, or ſilver, as they call it, which are frequently found arranged, in the ſtone, in the direction of the grain, or beat of the ſtone; which, it muſt be obſerved, is not always that of the beds or ſtratification, many rocks having ſtratula which croſs their beds obliquely, often at an angle, of from 30° to 45° with the bed or plane of the ſtratum; and ſuch ſtratula, not uncommonly, diſpoſe the ſtone to ſplit into flags or paviers or even tile-ſtones, or ſlates for houſes, and into the moſt thin and perfect lamina. Sometimes theſe oblique ſtratula croſs ſtone beds of very great thickneſs, and have been frequently miſtaken, by inattentive obſervers, for the ſtratification itſelf, as Mr. Kirwan obſerves of the argillites or ſlates, p. 283 of his "Geological Eſſays." See Stratula and Strata.

Grain, *Cochineal.* See Cochineal.

Grain, *Scarlet.* See Scarlet.

Grain, *Oily*, in *Botany*. See Myagrum.

Grain, *Tin.* See Streaming and Tin.

Grains, in the *Materia Medica*, or the ſeeds of vegetables, are diſtinguiſhed into emulſive, which yield a conſiderable quantity of mucilage and oil, which may be ſeparately extracted from them; ſuch are almonds, and the ſeeds of almoſt all fruits; and farinaceous, which are entirely compoſed of a dry ſubſtance, eaſily reducible into a fine powder, called meal. Of this kind are the grains of all graminous and leguminous plants.

Grains, in *Rural Economy*, a term applied to the remains of different ſubſtances of the grain kind after they have been employed in the brewing of beer, or the diſtillation of ſpirituous liquors. They are in much uſe by the farmers and cow-keepers near large towns for the feeding of various deſcriptions of domeſtic animals, ſuch as milch cows, hogs, fowls, geeſe, ducks, &c. as well as ſometimes for the fattening of neat cattle. In this laſt intention, it is however neceſſary to mix other ſubſtances with them, ſuch as good pollard, coarſe ground oatmeal, &c. It muſt be obſerved, that theſe matters can only be made uſe of while they are in a freſh ſtate with advantage. It is of courſe neceſſary, particularly during the more hot ſummer months, to employ ſuch means as are proper for preventing their running into a ſtate of fermentation, which would render them wholly uſeleſs. This is uſually effected by having them well preſſed and trodden down into large vats and ciſterns formed deeply in the ground, and covered from the action of the air. In this way they may be kept perfectly ſweet and fit for uſe for a conſiderable length of time. See Cow-keeping and Stall Feeding.

Grains *of Paradiſe.* See Medea.

Grain-*Coaſt*, *Malaguetta*, or *Pepper-Coaſt*, in *Geography*, a country of Guinea, extending about 300 miles along the coaſt of the Atlantic from the vicinity of Cape Palmos to that of the river Meſurada, but its limits are not preciſely aſcertained; and bounded by the country of the Foulahs, or the Sierra Leona country on the weſt, and the Ivory Coaſt on the ſouth-eaſt. It derives its name from the great quantity of Guinea pepper which it produces. The climate is inſalubrious, and is found to be particularly noxious to Europeans. The productions of this country are peaſe, beans, gourds, lemons, oranges, bananas, and a kind of nut with a thick ſhell, which is a moſt delicious fruit. The palm-wine and dates are in high perfection; cows, hogs, ſheep, and goats, are very plentiful; but this country derives its chief wealth from the abundance of Guinea pepper, or grains of Paradiſe, called Malaguetta by the Portugueſe, which it produces. It ſupplies alſo a conſiderable quantity of pimento. Its commerce has alſo very much conſiſted in ivory and ſlaves. The natives are reckoned temperate and abſtemious; but they are ſaid to allow Europeans every kind of familiarity with their females, and to invite them to love-banquets with their own wives and daughters. They are actuated in common with other negroes, by an invincible propenſity to ſteal, not only from ſtrangers and foreigners, but from the neareſt of their own kindred. Their language is peculiar to themſelves, and difficult of attainment. Their trade is carried on by ſigns and tokens, ſome of which are not very decent. The natives are, in general, well-formed, and handſome in their perſons and features. Their common dreſs is a "paan," or unſhaped piece of cloth round the waiſt. They are extremely ſubject to hernias and ruptures. They have among them ſome excellent mechanics, ſome of whom underſtand and practiſe the art of tempering ſteel, making arms, and all ſteel inſtruments, and conſtructing canoes; others have introduced improvements in huſbandry, particularly with reſpect to the method of cultivating rice, millet, and Guinea pepper. Their king, called "taba," "taba ſcyle," or "taba ſcil," exerciſes deſpotic authority over his ſubjects, and never appears abroad without the utmoſt pomp and magnificence; and he receives from the people a degree of veneration and awe, which belongs to ſuperior beings. They are ſaid to be believers in a future ſtate, which appears by the ceremonies performed to the ſouls of the deceaſed, and the prayers they offer for a happy meeting in another world. They welcome the new moon with ſongs, dancing, and every kind of diverſion; and their ſuperſtitious regard for ſorcerers is extreme.

The ſole employment of many of the negroes, eſpecially about the river Seſtos, is fiſhing, which they perform in their canoes by a hand-line and hook. The artiſts of Seſtos are alſo peculiarly expert in their manufacture of iron and metals.

The Portugueſe poſſeſſed for many years an independent and uncontrouled connection with this country; but in the year 1664 the Engliſh and Dutch, perceiving the advantages which were derived from their commerce, interfered, and their rivals prevailed to ſuch a degree as to drive the Portugueſe ſettlers into the interior parts of the country, where they united themſelves with the natives; and from this intercourſe ſprung that mixed progeny of Mulattoes, who are more numerous here than in any part of Guinea. The ſmall remnant of trade now poſſeſſed by the Portugueſe is entruſted with theſe perſons, to whom they give the appellation of the hidalgos or gentlemen, having proſelyted them to their forms of Chriſtian faith and practice, and initiated ſome of them into holy orders, whom they employ in propagating their notions of Chriſtianity.

The months moſt favourable to trade on this coaſt are February, March, and April; ſmall veſſels, which are capable of ſailing up the rivers into the country, are more convenient than large ſhips; and it ſhould be recollected, that the S.S.E. winds begin to blow in the month of May, and they bring with them heavy rains and tornadoes, with terrible thunder and lightning, extremely dangerous to ſhipping.

GRAINE, an iſland in the mouth of the river Thames, about 3½ miles long, and 2½ broad, ſeparated from the coaſt of Kent by a narrow channel, called the "Stray," or "Yenlade." It is low, flat, and marſhy, and has upon it only a number of detached huts, with ſome ſalt works. N. lat. 51° 27′. E. long. 0° 42′.

GRAINED MEDALS. See MEDAL.

Croſs GRAINED *Stuff.* See CROSS *Grained.*

GRAINGER, JAMES, in *Biography*, a phyſician and poet, was born at Dunſe, a ſmall town in the ſouth of Scotland, about the year 1723. After finiſhing his ſchool education, he was ſent to Edinburgh, where he commenced his medical ſtudies under profeſſors who were highly celebrated through the medical world, and in due time he received his degree of M. D. He commenced his profeſſional career as ſurgeon in the army, and in that capacity he ſerved in Germany, under the earl of Stair, till the peace of Aix-la-Chapelle, in 1748. He afterwards ſettled in London, and practiſed as a phyſician. He here obtained and cultivated the friendſhip of ſeveral diſtinguiſhed literary men, particularly of Shenſtone and Dr. Percy, afterwards biſhop of Dromore. While in London he publiſhed his tranſlation of the elegies of Tibullus; but this work did not receive the approbation to which he thought it entitled, eſpecially from Dr. Smollet, whoſe criticiſms were the occaſion of a long paper-war between them, and produced an irreconcileable difference. Probably his ſucceſs in practice in London was not great, as he embraced an offer of ſettling advantageouſly in the iſland of St. Chriſtopher, in the Weſt Indies; where, by marriage, he became connected with ſeveral of the principal families, and practiſed his profeſſion with great ſucceſs. He continued, however, to cultivate his attachment to the muſes, and wrote, during his leiſure hours, an intereſting poem "On the Culture of the Sugar Cane." He likewiſe compoſed a treatiſe "On the Diſeaſes of the Weſt Indies," for the uſe of the planters. At the concluſion of the war, he paid a viſit to his native country, and at the ſame time publiſhed his poem, with copious notes relative to the natural hiſtory of the iſland. He afterward returned to St. Chriſtopher's, and continued to practiſe till the beginning of the year 1767, when he was ſeized with a fever, which then raged in the iſland, and died. Dr. Grainger was benevolent in his diſpoſition, engaging in his manners, and an able phyſician: he ranks alſo conſiderably above mediocrity as a poet. An "Ode to Solitude," and "A Weſt Indian Ballad," (the latter publiſhed in Dr. Percy's collection) have been much admired. He publiſhed ſeveral medical tracts. Hutchinſon. Biog. Med.

GRAINGER, in *Geography*, a county of America, in the diſtrict of Hamilton, Teneſſee, formed of parts of the counties of Knox, Jefferſon, and Hawkins, and bounded N. by Virginia and Kentucky. Its chief town is Rutledge. It is very mountainous, interſperſed with fertile valleys. It contains 7367 inhabitants, of whom 496 are ſlaves.

GRAINING, in *Ichthyology*, the name of a fiſh found in the Merſey, near Warrington; it reſembles the dace, but is more ſlender, and has a ſtraighter back. See DACE.

GRAINING *Board* is a board uſed by the curriers, to give the grain to their leather.

It is made with teeth, or notches, running quite acroſs; into which the ſoft, moiſtened, ſuppled leather being preſſed, its ſurface readily takes the impreſſion. See CURRYING.

GRAINVILLE, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton, in the diſtrict of Les Andelys. The place contains 393, and the canton 10,846 inhabitants, on a territory of 185 kiliometres, in 32 communes.

GRAKLE, in *Ornithology*. See GRACULA and PARADISEA.

GRALLÆ, the fourth order of birds, compriſing thoſe which have the bill cylindrical, and a little obtuſe; tongue entire and fleſhy; and the legs naked above the knees.

GRALLATORIÆ. See CLASSIFICATION.

GRAMAT, in *Geography*, a town of France, in the department of the Lot, and chief place of a canton, in the diſtrict of Gourdon; 22 miles N.N.E. of Cahors. N. lat. 44° 47′. E. long. 1° 49′. The place contains 1842, and the canton 9888 inhabitants, on a territory of 275 kiliometres, in nine communes.

GRAMAYE, JOHN BAPTIST, in *Biography*, a writer of hiſtory, was a native of Antwerp, and flouriſhed in the early part of the 17th century. He ſtudied at Louvain, and became profeſſor of rhetoric in that univerſity. He was afterwards hiſtoriographer to the Low Countries, and obtained ſome other offices of truſt and honour. He travelled through the greater parts of Germany and Italy, and proceeding from the latter country to Spain, he was made captive by an Algerine corſair and carried to Africa. How he obtained his releaſe does not appear, but his writings prove that he had been an attentive obſerver of that country. Upon his return to his native land, he travelled into Moravia and Sileſia, and in the latter province he was, by cardinal Dietrichſtein, placed at the head of a college. He died at Lubec in 1635, leaving behind him many works, which ſhew that he was unqueſtionably a man of great learning. He wrote in proſe and alſo in verſe. Of the former are "Africæ Illuſtratæ, lib. x." 4to. 1622: "Diarium Algerienſe;" "Peregrinatio Belgica;" "Antiquitates Flandriæ;" and "Hiſtoria Namurcencis." The firſt of this liſt of works contains a hiſtory of Africa from the remoteſt periods to his own times, with geographical details; and the ſecond is the reſult of local obſervation during his captivity. Moreri.

GRAMEN, in *Botany*. See GRAMINA.

GRAMEN *Murorum, Micalongiſſima*. See FESTUCA.

GRAMINA, Graſſes, a moſt natural order of plants, the fourth of Linnæus, and the fourth order of the ſecond claſs in the Genera Plantarum of Juſſieu, who chooſes to alter the appellation of it to *Gramineæ*. The Latin word *gramen* is ſuppoſed to be derived from *gradiens*, going or proceeeding along, in alluſion to the great increaſe of many of theſe plants by their creeping roots.

Juſſieu's ſecond claſs conſiſts of monocotyledonous plants with a ſuperior germen. His definition of the preſent order is as follows.

Calyx, (which he terms *glume*,) ſingle or many-flowered, encloſing, in the latter inſtance, two or more flowers, diſpoſed in two ranks in a little ſpike or ear; it is moſtly of two valves, rarely of one or of many, or altogether wanting. Each flower has a *corolla*, (called *calyx* by Juſſieu,) reſembling the before-mentioned calyx, moſtly of two valves, rarely of only one, or altogether wanting; the outer valve either beardleſs or awned. *Stamens* below the germen, of a definite number, except in the *Pariana* of Aublet, generally three, rarely two, or ſix, or one; their anthers oblong, forked at each end. *Germen* one, ſuperior, accompanied at the baſe by two little ſcales, not always evident. *Styles* often two, with two feathery ſtigmas; ſometimes one, with a ſimple or divided ſtigma. *Seed* in either inſtance ſolitary, naked, or often clothed with the permanent inner valve of the corolla. *Embryo* ſmall, attached below to the ſide of the farinaceous and much larger *albumen*. The lobe of the embryo in germination is permanent and ſeſſile along with the annexed albumen, attached on one ſide, at the bottom, to the primary ſheath which ſurrounds the plumula, or bud of the future plant.

The *roots* are fibrous and capillary. *Stems* or *culms* cylindrical, either hollow or filled with pith, jointed or ſeparated into diſtinct portions by knots, moſtly ſimple and herbaceous. *Leaves* alternate, generally ſolitary at each knot of the ſtem, ſheathing, their ſheath ſplitting down to the knot. *Flowers* either in denſe cluſters, or ſpiked upon a common *rachis*, or panicled, concealed before they arrive at maturity in the ſheath of the upper leaf. Some ſpecies are monoicous, by an abortion of ſome of the organs.

Botaniſts have differed much about the principles on which the genera of Graſſes ſhould be founded. Linnæus and Juſſieu take into conſideration the number of flowers, or rather florets, in each calyx; Haller in a great meaſure rejects this, paying regard chiefly to the figure of the parts, which indeed is of primary importance. He does not, however, ſufficiently attend to other equally important marks, as the diſtinction, for inſtance, between *Poa* and *Briza*, conſiſting in the incorporation of the ſeed of the latter with the larger valve of the corolla, and its depreſſed figure. It were to be wiſhed that the awns of graſſes were permanent and conſtant in the ſame genus, or at leaſt ſpecies, but though conſtant in ſome, as *Avena*, in others, as *Agroſtis* and *Triticum*, they are not ſufficient to diſcriminate ſpecies.

In the ſexual ſyſtem Graſſes chiefly belong to *Triandria Digynia*. Some few have proper monoecious, none dioecious, flowers, and ſeveral are polygamous, having a few male bloſſoms intermixed with perfect ones furniſhed with both ſtamens and piſtils, and were therefore referred by Linnæus to *Polygamia*. But this latter circumſtance is ſo common and variable, and cauſes ſuch unnatural ſeparations of ſpecies or genera, that botaniſts have generally agreed to pay no regard to it in this family, but to claſs all ſuch graſſes by their perfect flowers.

Linnæus remarks that "Graſſes are the moſt general of plants, conſtituting almoſt a ſixth part of all the vegetables on our globe, eſpecially in open ſituations. There they multiply, and extend themſelves by creeping roots, to a vaſt extent. In confined and woody places they ſcarcely creep, but grow erect. They are the moſt important of plants, eſpecially as affording the chief ſuſtenance of animals who feed on vegetables. They furniſh the verdure of our ſummers, and ſpread a carpet over our meadows. Their leaves are not eaſily damaged, even by our walking over them; and though winter deſtroys their foliage, and the early ſpring finds them dry and withered, they revive in a wonderful manner from apparent death. How ſolicitouſly has the Author of Nature protected theſe plants, by giving them ſuch hard ſtems, while they are perfecting their ſeed, that cattle cannot readily attack them in that ſtate! Then, on the other hand, they are ſo conſtituted, that the more their herbage is cropped, or hardly uſed, the better they thrive, and extend themſelves the more under ground. That they may be able to exiſt in almoſt every ſituation, their narrow ſpiny leaves are purpoſely contrived to inſinuate themſelves between other plants.

"The creeping roots of graſſes are formed like a tapeworm; and are moſtly fibrous, rarely tuberous or bulbous. They conſiſt of numerous joints and knots, each of which has its bud, capable of producing a new ſtem, and the more they are ſeparated by the heavy tread of cattle, the more they multiply, thus conſtituting the ſtrength of the vegetable kingdom.

"Very few graſſes have any peculiar taſte, moſt of them having the inſipidity of pot-herbs, though ſome few are fragrant, at leaſt when dry. None are dangerous or poiſonous, if we except the intoxicating ſeeds of *Lolium temulentum*. They are the moſt ſimply conſtructed of all herbs, ſcarcely any of them having thorns, prickles, tendrils, ſtings, bracteas, or other appendages. Their ſtems are with us generally ſimple; in India frequently branched. Leaves always ſimple and undivided, moſtly quite flat, and if one ſide be ſomewhat rounded, it is never that next the ſtem. The ſheath of their leaves is often crowned with a membranous ſtipula, called by ſome *ligula*, which cloſely embraces the ſtem in growing, to keep out water.

"The fructification of Graſſes is ſo different from other plants that it was judged impoſſible to reduce them to order. They were firſt divided into Corn and Graſſes, but the former differ from the latter merely in the greater ſize of their ſeeds, which compoſe the baſis of our aliment, as the ſmalleſt of the graſs-ſeeds nouriſh ſmall birds. Ray firſt examined this tribe ſcientifically, dividing them by their habits or likeneſſes, but he traced out no juſt limits. Tournefort, though a moſt eminent botaniſt, was not equal to this ſubject. Monti followed Ray, but examined the graſſes of Italy only. John Scheuchzer, at the perſuaſion of Sherard, undertook ample and minute deſcriptions of every graſs he could procure, but the herbage of all is ſo ſimilar, that his deſcriptions, till he comes to the infloreſcence, are too little contraſted. They are, however, very exact. Micheli firſt contrived a method of arrangement founded on the ſpikelets being ſimple or compound, with an attention alſo to the ſexual parts; but he ſubjoined ſome plants, termed *graminibus affines*, which have really no connection with them. If the ſexes of graſſes be attended to, their arrangement becomes leſs difficult. Their infloreſcence is either ſpiked or panicled."

The principal writers on Graſſes, beſides thoſe abovementioned, are Schreber, who wrote in German, with fine plates, coloured or uncoloured, and who is very full on their qualities and uſes; Rottböll, who deſcribed new or rare ſpecies, with plates; Linnæus the younger, in a theſis deſcribing new genera of graſſes; Hoſt, who has publiſhed three folio volumes, with excellent coloured plates in the ſtyle of Jacquin, entitled *Gramina Auſtriaca*; Leers, who in his *Flora Herbornenſis* has delineated and engraved all the graſſes of that Flora, with more exquiſite preciſion than can be found in any ſimilar performance. Stillingfleet, Curtis, and Swayne have in England publiſhed botanical and economical remarks on graſſes, the latter giving dried ſpecimens to illuſtrate them. Many ſpecies are admirably repreſented and deſcribed in the *Flora Londinenſis*, and the ſecond part of the firſt volume of the *Flora Græca* contains 50 plates of rare and curious graſſes, from the drawings of Mr. Ferdinand Bauer, which are among the moſt beautiful and perfect of their kind.

The number of genera of graſſes in Juſſieu are 60, arranged in 13 ſections, nine of which comprehend graſſes with two ſtyles, four thoſe with only one. This diſtinction however is not one of the moſt abſolute, even in the ſame genus. His ſubdiviſions are marked by the number of ſtamens, or of florets, according to what we have mentioned above.

Willdenow has in his *Triandria Digynia* 34 genera, beſides five in *Triandria Monogynia*, *Cinna* in *Monandria*, and *Nardus* in *Diandria;* he has moreover, in *Hexandria*, *Ehrharta*, and *Oryza*, in all 43. He has five genera in *Monoecia*, making 48 in the whole, beſides the polygamous ones, which after the original plan of Linnæus, he refers to *Polygamia*. We have not yet ſeen this latter part of his work. In the 14th edition of Linnæus's *Syſtema Vegetabilium* the genera of polygamous graſſes are eight, only, *Holcus*, *Cenchrus*, *Iſchæmum*, *Maniſuris*, *Ægilops*, *Spinifex*, *Andropogon*, and *Apluda*. Willdenow places *Cenchrus* in *Triandria Monogynia*, we believe with great propriety, but the genus appears unnatural with reſpect to habit, and perhaps requires to be new modelled.

Mr. R. Brown, in his *Prodromus Floræ Novæ Hollandiæ et Inſulæ Van-Diemen*, has defined 35 new genera of this natural order; *Sporobolus* ſeparated from the Linnæan *Agroſtis;* *Polypogon* of Desfontaines; *Pentapogon* of Billardiere; *Streptachne* very near *Stipa;* *Amphipogon* remarkable for having an awn to each of the five ſegments of its corolla; *Diplopogon* apparently too nearly akin to the laſt; *Aniſopogon* very near the following; *Danthonia* of Decandolle; *Glyceria* of which we have treated in its proper place; *Triodia* very near *Poa;* *Eriachne* ſomewhat akin to *Aira;* *Triraphis;* *Ectroſia;* *Eleuſine* of Gærtner; *Chloris* of Swartz; *Cœlachne* remarkable for having its imperfect flower female, not, as uſual in graſſes, male; *Chamæraphis* diſtinguiſhed from *Panicum* chiefly by the peculiarity of three ſtyles; *Orthopogon* formed of Linnæus's *Panicum compoſitum* and others; *Penniſetum* of Richard; *Neurachne* reſembling an *Alopecurus;* *Iſachne* to which belongs the *Meneritana* of Herman's Zeyl. 24; *Xerochloa* whoſe ſeed is incloſed in the *inner* paper-like valve of the corolla; *Thuarea* of Thuars in Perſoon's Synopſis; *Imperata* of Cyrilli, which is *Lagurus cylindricus* of Linnæus; *Dimeria* near *Saccharum;* *Ophiurus;* *Lepturus;* and *Hemarthria;* the three laſt ſeparated from *Rottböllia;* *Microchloa* which is *Nardus indica* of Linnæus; *Zoyſia* recently formed by Willdenow of his *Agroſtis Matrella;* *Hierochloe* of Gmelin Sibir which is *Diſarrenum* of Billardiere; *Tetrarrhena* compoſed of the *Ehrharta diſtichophylla* of Billardiere with other ſpecies; *Microlæna* his *E. ſtipoides*; *Potamophila* a water graſs near *Oryza* and *Zigania;* and finally *Leptaſpis* which has the aſpect of *Pharus latifolius*.—It is not wonderful that a country whoſe natural productions are all ſo very anomalous with reſpect to thoſe of the reſt of the world, ſhould afford ſo many novelties, even in ſo natural and well-known a family as the graſſes.

GRAMINEA, in *Antiquity*, is applied to a crown formed of graſs, *gramen*, beſtowed by the Romans on certain of their generals, in conſideration of their having ſaved or reſcued an army.

The graſſy crown, *corona graminea*, was but rarely conferred, and for ſome ſignal exploit; when, through the courage or dexterity of a general, an army reduced to the laſt extremities had been ſaved, or delivered, and the enemy put to flight.

GRAMINEOUS HERBS, among *Botaniſts*, are ſuch as have a long, narrow leaf, with no foot-ſtalk.

GRAMINIFOLIA, a name given by Dillenius to a genus of plants, called by Micheli and Linnæus zannichellia.

GRAMMAR, teaches the right uſe of language, or to ſpeak, to read, and to write a language with propriety. Particular grammar teaches the principles peculiar to any one language. Thus the Engliſh grammar aſcertains and teaches the principles which excluſively belong to, and which diſtinguiſh the Engliſh tongue. The French grammar profeſſes the ſame end with regard to the French; and this is the caſe with the grammar of any other language.

When grammar is limited to any particular language, it is employed in its humbleſt province, and may be conſidered only as a mere *mechanical art*, the rules of which are little inveſtigated, and have no other foundation than the practice of thoſe who ſpeak and write that language. But when grammar, riſing above the conſideration of any one language, compares many languages together, and by this compariſon traces the principles which are common to them, unfolding by that means the nature and origin of ſpeech, the cauſes by which it is divided into diſtinct dialects, and the analogies which facilitated the growth and determined the idioms of each: grammar, in this extenſive view, aſſumes the nature of a *ſcience*, and is juſtly diſtinguiſhed by the name of *general* or *univerſal grammar*.

That grammar claims the dignity of a ſcience, in conſequence of inveſtigating the general principles of ſpeech, is evident from the ſlighteſt conſideration. All languages, however different, have many properties in common. They have in general the ſame parts of ſpeech, becauſe the ideas or things which they expreſs exiſt with little or no variation in the nature of things. Men alſo, in all ages and countries, have the ſame organs of ſpeech, which are ſimilar in ſtructure, however modified by peculiarities of enunciation. Finally, the ſame great law of aſſociation regulates the mind of every man; and the political, moral, and religious inſtitutions, which direct the operations of this law, however remote in age and country, conſiderably reſemble each other. To theſe cauſes it is owing, that the languages of all nations, ancient and modern, are marked by a ſimilitude truly ſurpriſing; and the more cloſely they are examined, the more numerous will appear the points in which they all reſemble each other. Hence may be juſtified the concluſion, that as all the tribes of men originated in one family, ſo all the languages of men are but ramifications of one original tongue.

Grammar has uſually been divided into four departments, namely, *orthography*, *etymology*, *ſyntax*, and *proſody*. Orthography teaches to form and to ſound letters, to analyſe or combine ſyllables, or to expreſs words by their proper letters. Etymology comprehends the claſſification, the properties, or, more properly ſpeaking, the derivation and compoſition of words. Syntax preſcribes the government or the right order of words in a ſentence; while proſody directs the juſt pronunciation, the poetical conſtruction of words, or ſupplies the laws of verſification. But this diſtribution of the parts of grammar is neither uſeful nor accurate, as they are not independent of each other. Etymology is a principle neceſſary to account for phenomena in every department, and is that upon which orthography is chiefly founded. We therefore diſcard theſe diviſions of grammar, and diſtribute and confine our obſervations on this ſubject to the origin, nature, claſſification, and the properties of words.

The Origin, Nature, and Claſſification of Words.

Words have been defined articulate or ſignificant ſounds, formed by the organs of ſpeech, and uſed by common conſent as ſigns of ideas. The propriety of this definition will appear, if we attend to the mode in which words acquire their ſignification. The beſt method to teach a language, with which a youth is yet entirely unacquainted, would, if attended to, clearly unfold the nature and origin of ſpeech in general. Suppoſe a *book* is held out before him for the firſt time, an *impreſſion, phantaſm,* or *idea* of that object is thus conveyed to his mind by the organ of ſight. While this impreſſion continues, ſuppoſe farther that the *ſound* book is diſtinctly uttered; he will then have an impreſſion or idea of the ſound conveyed through the ſenſe of hearing, which will be rendered more diſtinct, if he himſelf be taught to enunciate it. The two ideas, namely, that of the *object*, and that of the *ſound* will then, if long continued, or often repeated, coaleſce in his mind, and become ſo ſtrongly connected, that the idea of the object ſhall ſuggeſt that of the ſound, book: and, on the other hand, the ſound ſhall recal the object. The principle on which this coalition is founded, is a law of the human mind, known under the name *aſſociation of ideas;* and the progreſs of the learner in connecting other ideas with other ſounds, is only a repetition of the operation, till the whole language is acquired.

From this brief deſcription, naturally follow a few inferences of importance, to be obſerved on this ſubject. *Firſt*, ſounds, though ſo cloſely connected by frequent uſe with the things ſignified, as not to be ſeparated from them even in imagination, have no natural affinity with them. Any other ſound than *book*, *moon* for inſtance, might have been aſſociated with that object in the mind of a learner, and this laſt name would as naturally, by uſe, be applied to book, as we now apply it to the object ſo known in the ſky. And this is the reaſon why the ſame idea is expreſſed by different ſounds in different countries, where each ſound is rendered equally natural and familiar by repeated aſſociations. *Secondly*, as language altogether depends on an arbitrary compact between ſound and ſenſe, there exiſt not, in any regular poliſhed tongue, ſuch words as *natural* articulate ſounds. There are, indeed, in all languages, certain ſounds indicating deſire or averſion, pleaſure or pain, but theſe are natural cries, and not articulate ſounds; and they ariſe more from the ſtructure of man as an animal, than from his rank as an intelligent being, capable of forming diſtinct ideas, and expreſſing them by articulate ſounds. Hence ſuch ſounds are common to him with inferior animals, and abound moſt among men in the ſavage ſtate, where language is leaſt formed. The above explanation farther excludes what have been called *factitious* words, or words whoſe ſound bears ſome reſemblance to the ſenſe. Some words indeed, of this kind, are ſuppoſed to exiſt in all languages; but the ſuppoſition, we venture to affirm, is erroneous, the imagined ſimilarity being altogether the effect of aſſociation. This principle, when a word is heard, inſtantly ſuggeſts its meaning, and while we overlook the ſuggeſtion, we aſcribe the ſenſe to a fancied ſimilitude between it and the ſound. Let an idea be in your mind, when you hear a *cock crow*, or a *bell toll,* and you will immediately ſuppoſe, that the ſound of the cock, or of the bell, conveyed the entertained idea. This is a deluſion preciſely ſimilar to that into which we fall reſpecting the import of factitious words. If there be any word in our language, or in any language naturally indicative of the ſenſe, it is *cuckoo;* and yet aſk a foreigner, altogether unacquainted with Engliſh, what the term means, and he will not by any means be able, from the ſound, to aſcertain the object ſignified. The word is a repetition of *coo coo*, which exiſts in Greek under the form of γοαω, and which in Perſian ſignifies the ſound made by a ſtrong emiſſion of the breath. Hence the Perſians expreſs the *ox-kind* by *caa*, which we have borrowed and confined to the female *cow*, which originally meant a *lowing* animal. In Chaldee, *cuckeo* means a *magpie*, the ſound of whoſe voice is very different from that of the cuckoo. We cannot help remarking, that if a ſimilitude between ſound and ſenſe obtained in any part of language, it would appear more manifeſt and predominant in the moſt *ancient* languages, and eſpecially in Hebrew, which we conceive by far the moſt ancient, even of the Aſiatic tongues. But we venture to affirm, that not a ſingle inſtance of the kind can be produced in that tongue. And this early ſpecimen of human language is a fair preſumption, that the principle of factitious ſounds did not in the leaſt obtain in the firſt formation of ſpeech.

From the above explanation we infer, in the *third* place, that the names of things, at firſt, were names of *individual* objects, and that man learnt in youth, to form *general* ideas, *ſolely by means of language.* Thus with reſpect to the above-mentioned youth, when he has connected the ſound book with the thing ſo called, the word is only a ſign of the individual book which was firſt preſented to him. Preſently, however, he perceives the ſame ſound applied ſucceſſively to other objects of the ſame kind; and this application leads, and in a manner *compels* him to note thoſe peculiar circumſtances which diſtinguiſh each book, and thoſe, on the other hand, which belong to that whole claſs of objects. As the ſound is not repeatedly aſſociated with the former, he *forgets*, and conſequently *overlooks* them; while he combines the ideas belonging to the claſs, and retains them in a cloſer and yet cloſer union, under the term which was his inſtrument in forming thoſe ideas. In this manner are all our *abſtract ideas* acquired; and language, as the mind riſes by means of it, from the contemplation of one to many objects, from individuals to claſſes, is the ſole inſtrument in acquiring them. Some indiſtinct idea of this proceſs was probably the circumſtance which led our celebrated grammarian, Mr. H. Tooke, to ſay, (vol. i. p. 36.) "That the compoſition of ideas was merely a contrivance of language; that the only compoſition was in the *terms*, and that they are not ideas, but merely terms which are general and abſtract." In another place, he denies the operations of the mind as influencing ſpeech, and talks of the operation of language. Theſe, and ſuch other remarks are, however, ſo palpably erroneous, that we cannot aſcribe it to ignorance or inattention in ſo enlightened a critic, but ſuppoſe them to have proceeded chiefly from a deſire which pervades his works, of rejecting the ideas of others as unjuſt, becauſe they were *known*, and conſpicuouſly diſplaying his own as right, becauſe they were *new*. The compoſition of terms in grammar, is merely the derivation or combination of terms, by ſuch laws as cuſtom or analogy have previouſly determined. Compoſition of this kind, with which a grammarian, as ſuch, has any thing to do, is as diſtinct from the compoſition of ideas, as ſound is from ſenſe, or grammar is from logic. Language has no power but what it has derived from *aſſociation;* and he who ſpeaks of the operation of language, inſtead of the operation of the mind, acts the abſurd part of a man who aſcribes to the pen, the motion of the hand which directs it. If we can judge from his works, Mr. Tooke appears not to have ſtudied the true theory of the human mind; and from the want of juſt ideas on this ſubject, he has, as we ſhall ſhew in the ſequel, plunged himſelf and his readers in deep and manifold errors.

As general or abſtract ideas, which are the chief materials of ſcience, are formed ſolely by the inſtrumentality of language, we may hence ſee the reaſon why the ſtudy of language ought to form the *baſis* in every ſyſtem of education; and why ſcience can flouriſh only among a people previouſly acquainted with the arts of eloquence and compoſition. The philoſophy of grammar, moreover, as it retraces the track of the human mind, in the formation of its ideas, through the medium of ſpeech, is the beſt guide to the knowledge of its powers and operations, and conſequently to their proper direction. Hence the only ſyſtems of metaphyſics and logic, worthy the attention of a philoſophical enquirer, are thoſe which are built on the foundation of grammatical analyſis.

But further, as words in the very commencement of every man's education denote individual objects, and become ſigns of claſſes or kinds by the ſucceſſive application of each word to many individuals of that claſs, we might conclude that in the original language of mankind, if ſolely the effect of human invention, each term at firſt was but a proper name of a thing or of a quality, and afterwards repreſented a greater number of individuals as the mind advanced in the principle of generalization. But this inference is contrary to the fact. The Hebrew tongue carries us back almoſt to the infancy of human ſociety, and, whether it be the original language of mankind or not, it preſents us with much fairer ſpecimens of what language muſt have been, than we can gather from any modern dialect. The primitive words of that language are founded upon the moſt comprehenſive analogies; and the learner, in acquiring that tongue, inſtead of being carried up from the individual to the ſpecies, and from the ſpecies to the genus, finds himſelf on the top of the moſt extenſive claſs; and in the formation of words he is made to deſcend from general to ſpecific terms, and from ſpecific terms to proper names; ſo that all the proper names which we meet with in the Hebrew records are really derived from general appellations. This phenomenon appears to us completely to annihilate the ſuppoſition, that language is ſolely the fruit of human ingenuity. Moſes, in his hiſtory, obliquely ſtates, and, with his uſual brevity, accounts for the fact: "And out of the ground the Lord God formed every beaſt of the field, and every fowl of the air, and brought them *to ſee* what he would call them: and whatſoever Adam called every living creature, that was the name thereof." The Arabic tranſlation, we apprehend, alone places this verſe in its proper light, by rendering *to ſee*, to cauſe *to ſee*, *i. e. to ſhew*. The author then intimates that God ſhewed or directed Adam in the application of names to things. And what can be more probable, than that *He*, who formed the organs of man, ſhould at firſt inſtruct man in the proper uſe of them.

Laſtly, it follows from the above explanation, that words, as they are at firſt aſſociated with ideas, are in ſtrict propriety ſigns of *ideas*, and not ſigns of *things*. For unleſs the idea be previouſly in the mind, there can be no union by aſſociation of ſenſe with ſound. The aſſociation takes place in the mind, and where the idea of the thing, and that of the ſound do not meet, there can be no formation of articulate ſound. The learner, however, is not ſenſible of any diſtinction between his ideas and the external objects which are their origin or prototypes; and he refers the ſound immediately to its prototype, without being conſcious that an impreſſion or idea of it exiſts in his mind. As, however, we know nothing of things but through the medium of our ideas, and as ideas muſt depend for their properties and diſtinction upon the things they repreſent, the above overſight is not productive of any error or inconvenience; and we may ſay that words are ſigns of things, or of the ideas of things, without any prejudice to philoſophical accuracy. This leads us to the claſſification of ſpeech, or its diviſion into parts.

The common diſtribution in our own tongue is into *nouns*, *articles*, *adjectives*, *pronouns*, *verbs*, *participles*, *adverbs*, *prepoſitions*, *conjunctions*, and *interjections*. This diviſion has obtained with little variation in other modern languages, and has been derived, on the authority of ancient grammarians, from the languages of Greece and Rome. The above claſſification, however general and convenient in a popular view, is by no means to be admitted in a philoſophical grammar. And the few writers of this kind in Engliſh, or other tongues, have been ſenſible of the inaccuracy of the popular diviſion. The Oriental grammarians admit only *three parts* of ſpeech, the verb, the noun, and particles derived from theſe. Plato, whoſe notion of language as a ſcience muſt have been formed in Egypt, mentions only two, the noun and the verb; tom. i. p. 261. Edit. Ser. And Ariſtotle mentions no more, where he treats of propoſitions. (De Inter. c. 2.) But Mr. Harris, Herm. p. 38. thinks that thoſe philoſophers were not ignorant of the other parts of ſpeech, but ſpoke with reference to logic or dialectics, conſidering the eſſence of ſpeech as contained in theſe two, becauſe they alone combined to make a perfect aſſertive ſentence, which none of the reſt without them are able to effect. But Ariſtotle, in his treatiſe of Poetry, where he was to lay down the elements of a more variegated ſpeech, adds the *article* and *conjunction* to the noun and verb. The latter Stoics, improving on the authority of Ariſtotle, inſtead of *four* parts, made *five*, by dividing the noun into the *appellative* and *proper*. Others increaſed the number, by detaching the *pronoun* from the *noun*; the *participle* and *adverb* from the verb; and the *prepoſition* from the conjunction. The Latin grammarians went farther, and detached the interjection from the adverb, within which by the Greeks it was always included as a ſpecies.

Mr. Harris, following Ariſtotle and the elder Stoics, divides ſpeech into words that are ſignificant as *principals*, and thoſe which are ſignificant as *acceſſories*, including under the former claſs *ſubſtantives* and *attributives*, and under the latter *definitives* and *connectives*. This diſtribution is ſet aſide and ridiculed by Mr. Tooke, who ſays, vol. i. p. 47; "In Engliſh, and in all languages, there are only two ſorts of words, which are neceſſary for the communication of our thoughts, and they are noun and verb. And as to the parts of ſpeech, they may be either *two* or *twenty*, or more. In the ſtrict ſenſe of the term, both the neceſſary words and the abbreviations are all of them parts of ſpeech; becauſe they are all uſeful in language, and each has a different manner of ſignification. But I think it of great conſequence, both to knowledge and to languages, to keep the words employed for the different purpoſes of ſpeech as diſtinct as poſſible. And therefore I am inclined to allow that rank only to *neceſſary* words: and to include all the others, which are not neceſſary to ſpeech, but merely *ſubſtitutes* of the firſt ſort, under the title of *abbreviations*." In this boaſted diviſion, as we ſhall preſently ſee, there is neither utility nor accuracy, and the author was betrayed to it by a ſecret wiſh to place the novelty of his own ſyſtem in the moſt conſpicuous light, namely, that conjunctions and prepoſitions are but abbreviations of nouns and verbs.

Now it is ſingular, that the diviſion which we think the moſt philoſophical, and, therefore, the moſt ſimple and uſeful, is that which is thus proſcribed in a very laboured treatiſe on grammar, in the Encyclopædia Britannica, (article 11.) "The diviſion of words into thoſe which are *ſignificant of themſelves,* and thoſe which are *ſignificant by relation,* is abſolute nonſenſe, and has been productive of much error and myſtery in ſome of the moſt celebrated treatiſes on grammar. It is indeed probable, that any attempt to eſtabliſh a different claſſification of the parts of ſpeech, from that which is commonly received, will be found of little utility, either in *practice* or in *ſpeculation.* As far as the *former* is concerned, the vulgar diviſion ſeems ſufficiently commodious; for every man who knows any thing, knows when he uſes a noun, and when a verb. With reſpect to the *latter,* not to mention that all the grammarians, from Ariſtotle to Horne Tooke, have differed on the ſubject; it ſhould ſeem to be of more importance, after having aſcertained, with preciſion, the nature of each ſpecies of words, to determine in what circumſtances they differ than in what they agree."

If theſe remarks be juſt, any attempt at a philoſophical arrangement of the parts of language muſt be frivolous and uſeleſs. But we regard the paragraph as a manifeſt acknowledgment that the writer knew of no ſuch arrangement, and that, as is often the caſe, he endeavours to conſole himſelf and his readers, under the abſence of this knowledge, with the conſideration that if attained it would not be uſeful. We ſhall, however, attempt briefly to do what he thinks unneceſſary to be done: but what we think not only uſeful and neceſſary, but even eſſential, in a philoſophical treatiſe. An accurate diſtribution of our words, is but an accurate diſtribution of our ideas; and as in logic we cannot think juſtly, unleſs we know how to diſtinguiſh our thoughts; ſo we cannot with preciſion reaſon in grammar, unleſs we have previouſly diſtinguiſhed the parts of ſpeech. The ſource of this diſtinction muſt be ſought in the nature of the ideas expreſſed by thoſe parts, and the enquiry, how many ſorts of words there exiſt in human language, is merely, when directed to its proper object, how many ſorts of ideas there are in human knowledge.

We have then ideas of *things:* we have ideas of the *properties* or *attributes* of things: we have ideas of the *connection* of things, *i. e.* of the arrangement of things, or of their increaſe or diminution: finally, we have ideas of the *relation* of things. Nor have we an idea which may not rank with one of theſe claſſes. And as language conſiſts of terms expreſſing ideas, it conſiſts of terms which expreſs either ideas of *things* or the *attributes* of things, or the *connection* of things, or the *relation* of things. The terms expreſſing things are *nouns,* including ſubſtantives and the perſonal pronouns, which are only *ſubſtitutes* for nouns, and therefore, in their nature, names of things. *Sweet* is an attribute of ſugar, and ſo is *to think* an attribute of a man; *to fly* of a bird; *to be* of a being that exiſts, and ſo, moreover, *loving, hating,* are attributes of ſome creatures ſuſceptible of love and hatred; finally, the circumſtances which define things or diſtinguiſh them from others, may be conſidered as attributes or properties of the things ſo defined. The terms expreſſing attributes may be called *attributives;* and include adjectives, verbs, adverbs, participles, and definitives. The terms expreſſing the relations of things are prepoſitions; while thoſe which expreſs the connection of things are conjunctions. And thus the moſt comprehenſive, and, as we conceive, the moſt philoſophical diviſion of ſpeech is into four parts, *nouns, attributives, prepoſitions,* and *conjunctions* or *connectives;* nor is there any language, however few or numerous its terms may be, which is not capable of being diſtributed into theſe four claſſes. As to the *interjection,* it muſt be regarded as a ſound which is either inarticulate, or which, as far as it partakes of articulation, partakes of the nature of a noun or of a verb. Having noted this diſtribution, we, as not ſyſtematically writing on grammar, ſhall, in our remarks, follow the popular diviſion.

Nouns and attributives, to uſe Mr. Harris's language, are ſignificant as *principals,* and we do not depart from philoſophical accuracy, when we ſay that prepoſitions and connectives are ſignificant by *relation.* Our notions of the relations and connections of things ariſe by the principle of abſtraction from our notions of the things themſelves ſo related or connected. If all ideas of things or actions were obliterated from our minds, the ideas of their aſſociated relations would be entirely obliterated with them. And as our notions of relation ſpring from the objects ſo related, ſo language, following the riſe and progreſs of ideas, has derived thoſe terms which expreſs relations and connections, from the terms expreſſing the things and operations ſo related and connected. In other words, prepoſitions and conjunctions are words which, by aſſociation, flowed from nouns and verbs as their real ſources. If this be correct, what ſhall we ſay to Mr. H. Tooke, who affirms prepoſitions, conjunctions, and other particles, to be ſubſtitutes for thoſe neceſſary words, the noun and verb. If this aſſertion be put in clear language, it means that the relations of things, or of the operations of things, are *ſubſtitutes* for the things ſo related; that is, the relation of *cauſe* and *effect* is a ſubſtitute for cauſe and effect; the relation of *beginning* is a ſubſtitute for things which begin; the relation of *inſtrumentality* is a ſubſtitute for that which is inſtrumental; and the relation of *end* is a ſubſtitute for that which ends. Moreover, the ſeparation or concatenation of two or more aſſertions is a ſubſtitute for the operations ſo ſeparated or connected. This is not philoſophical reaſoning, calculated to throw light on language, but a ſophiſtry calculated to confound the moſt diſtinct ideas which the human mind is capable of forming, and a jargon not to be equalled by any error or contradiction, which Mr. Tooke has ſo ſeverely cenſured and ridiculed in Mr. Harris. Beſides, terms to expreſs the relations and connections of things are not leſs neceſſary than thoſe which denote things and their operations. A language without conjunctions and prepoſitions is not merely a ſledge, (to uſe his own words,) which cannot be drawn along as ſmoothly, and eaſily, and ſwiftly, as a carriage with wheels, but is a ſledge which has nothing to connect it with the horſe; nothing to direct it in the way along which it ſhould be dragged. The noun and the verb indeed may expreſs a complete propoſition; but the inſtances in which ſuch ſimple propoſitions occur are very few, compared with thoſe more complicated caſes where the uſe of prepoſitions and connectives is abſolutely neceſſary. The diſtribution of ſpeech into neceſſary words and abbreviations, is therefore, in this point of view, alſo frivolous and erroneous.

The Origin and Properties of Nouns.

Nouns are the names of things, or ſigns of thoſe ideas by which we come to the knowledge of things. The term is a corruption of *nomen,* which is from ονομα, while *name* came probably from the Perſian *naam,* which ſeems to be of the ſame origin with the Greek word. Nouns may be divided into three claſſes: names of *individuals,* names of *ſpecies* or *kinds,* names of *abſtract ideas.* To this may be added, as a fourth claſs, the *pronoun,* which is made the ſubſtitute or repreſentative of all other nouns. But we ſhall conſider this in the place uſually aſſigned to it by grammarians. On each of the above claſſes we beg to make a few brief remarks.

'Names of individuals do not enter into the compoſition of language; becauſe individual objects are too numerous to have each a diſtinct name; and becauſe language would then be changing in endleſs ſucceſſion, each term dying away with the object it ſignified, and another riſing to occupy its place. This is the reaſon why *proper names* cannot be tranſlated from one tongue to another, the individuals ſpecified by them, being confined to one time and one place, are not capable of being the prototypes of words in other times and places. Individuals, however, among men, animals, and places, which the purpoſes of life render it neceſſary to ſpecify, have appropriate names given them to diſtinguiſh them from all other individuals. And it ſometimes happens that when individuals among men become eminent for any attainment or profeſſion, their names are uſed to deſignate others who are eminent in the ſame way. Thus proper names are ſometimes converted into common names.' The former are called proper, as being peculiar to individuals, in oppoſition to ſuch names as are common to all the individuals of a claſs.

The perceptions of the human mind, as we have obſerved, commence with individual objects: but we are ſoon induced to compare thoſe objects; and on comparing individuals together, we readily diſcern a reſemblance between them in ſome things while they differ in others. The mind then ſeparates the particulars in which objects *differ*, and collects into one idea their points of ſimilitude. Thus it forms ideas of claſſes, or in logic called *ſpecies*, comprehending under them various individuals. After this the ſpecies themſelves ſoon become ſubjects of compariſon; and excluding from each its individual qualities, the human mind formed thoſe more general aggregates termed *kinds*, comprehending under them different ſpecies, as the ſpecies comprehend different individuals. Thus mankind claſſified all the objects around them, and acquired ſpecific and generic ideas in nature, in art, and in abſtract qualities. Having, as it is ſuppoſed, firſt advanced in the claſſification of their ideas, men gave names to each claſs, and thus acquired thoſe general terms which are called ſpecific and generic terms. But we have already ſhewn that the proceſs of the human mind, in the principle of abſtraction, is the reverſe of this: general terms do not ariſe, as will appear evident if we attend to the commencement of education in ourſelves and others, from general ideas, but, on the contrary, general ideas ariſe from general terms. The former have no exiſtence till they are generated in the mind ſolely by the inſtrumentality of language; the learner being *involuntarily* and *paſſively* led by the ſucceſſive application of the ſame word to different individuals of the ſame claſs, to compare them, to ſeparate their component parts where they differ, and to combine them where they agree. In this point of view, grammar is the foundation of logic; and language, inſtead of being the offspring of human invention, is the ſole medium of awakening the firſt dawn of intelligence in the human mind, and points for its exiſtence to ſome intelligence ſuperior to man.

Specific and generic ideas being thus formed, the ſubject matter of language is reduced, ſo as to be *commenſurate* with the limited faculties of man; becauſe, though individual objects are infinite, the claſſes comprehending them are comparatively few. The ſubject matter of ſpeech by this means, moreover, is rendered *permanent* and *univerſal*, or unconfined to points of ſpace and time; becauſe, though particular things are local and tranſient, the ſpecies and kinds of things are univerſal and eternal. This is the reaſon why words which are unintelligible in one age and country are underſtood in other ages and countries; and may be tranſlated from one tongue into another, without ambiguity or error, where the prototypes exiſt in common. Farther, though general terms are often indefinite and uncertain, yet whenever they expreſs ſpecies or kinds, they may be defined by aſcertaining the ſeveral ideas which conſtitute thoſe ſpecies or kinds. And as the properties which conſtitute each claſs are found complete in each individual of each claſs, the name of the kind is applied to each of the ſpecies; and the name of the ſpecies to each individual included under it: and thus generic and ſpecific terms are employed by the aſſiſtance of certain adjuncts hereafter to be conſidered, to denote individuals.

General ideas may be conſidered as abſtract ideas, as they are generated by the mind *ſeparating* or *abſtracting* from each object thoſe particularities which conſtitute individuality. But they are to be diſtinguiſhed, at leaſt in a grammatical view, from that numerous and important claſs of ideas which we acquire by the more ſimple act of ſeparating from a thing the quality which belongs to it. Thus, the attribute *to think* becomes *thought*; and *good* is converted into *goodneſs*. Abſtract nouns of this kind are all, without exception, derived from *verbs* and *adjectives*, and formed by the ſimple power of withdrawing a property from the ſubject which ſupports it, and giving it an independent exiſtence in the imagination. Now, it is a fact worthy of attention, that as general, ſo abſtracted, ideas are formed by the ſole agency of language, and would not have exiſted in the ſlighteſt degree, if words had not previouſly been applied to expreſs the qualities of things. For as ſoon as a property was marked by an appropriate word, the ſeparate and independent exiſtence of that word, recognized by the eye or by the ear, induced the mind, without an effort and, perhaps imperceptibly, to give the property ſo deſignated an independent exiſtence alſo. Mr. Tooke rejects the principle of abſtraction, and would introduce in the room of it what he calls *ſubaudition*. Thus, according to him, *goodneſs* is that which is good; *flying* is that which flies: and under this erroneous and circuitous mode of explaining abſtract qualities which he has borrowed from the neuter participle in Latin, he has attempted to bury out of ſight the operation of the mind in forming abſtract ideas. The exiſtence of this operation, however, is too obvious to be denied with effect, and too important, in philoſophical grammar, to be abandoned on the authority of any perſon whoſe acuteneſs of intellect may enable him ſometimes rather to perplex than to unravel truth. In conformity to his own theory, Mr. Tooke ſuppoſes ſuch words as *ſcience*, *diligence*, which are abſtract nouns, derived from the Latin *ſcientia*, *diligentia*, to be neuter participles plural in *entia*, a ſuppoſition contrary to the analogy of the Latin tongue, which affords not a ſingle inſtance of plural adjectives being converted into abſtract nouns.

We cannot help noticing in this place an obſervation in the Encyclopædia Britannica, 13; "As all the objects which exiſt muſt be either in the ſame ſtate in which they were produced by nature, or changed from their original ſtate by art, or abſtracted from ſubſtances by the powers of imagination, and conceived by the mind, as having at leaſt the capacity of being characterized by qualities; this naturally ſuggeſts a diviſion of nouns into *natural*; as *man*, *vegetable*, *tree*, &c.; *artificial*, as *houſe*, *ſhip*, *watch*, &c.; and *abſtract*, as *whiteneſs*, *motion*, *temperance*, &c." This diviſion has been borrowed from Mr. Harris, in his Hermes, and borrowed without conſideration. Abſtract ideas are the chief materials of ſcience, which, giving birth to art, extended to the productions of art, as its genuine offspring, the uſe of its own terms. Accordingly, all *artificial* terms are abſtract terms, or terms derived from adjectives and verbs. Thus, *ſtable* denotes an artificial production, and is at the ſame time an abſtract noun from *ſtabilis;* and *plough* is taken from the Hebrew פלג, *phalag*, and means an inſtrument of ſeparation. And even natural objects are often expreſſed by abſtract nouns, as *creation* from the verb *create*. And if abſtract nouns are extended by aſſociation to deſignate natural and artificial objects, they cannot with propriety be ſaid to form a claſs of nouns diſtinct from nature and art.

Abſtract nouns, expreſſing ideas properly ſo called, are very numerous in our language, and worthy of attention. They are chiefly taken from the Latin; as thoſe in *tion* or *ſion*, *ment*, *ence*, *ty*, or *tude;* as *faction*, *colluſion*, *commandment*, *conſequence*, *piety*, *altitude*. And all the nouns of this termination, with others in *nſe* and *t*, ſuch as *expanſe*, *merit*, are alſo from this ſource. Many others are derived from the Anglo-Saxon or Gothic, ſuch as all thoſe in *neſs*, *ſome*, and *hood;* as *goodneſs*, *noiſome*, *neighbourhood*. The far greater part of Mr. Tooke's ſecond volume is occupied in tracing nouns of this deſcription. His etymological reſearches are, in many reſpects, uſeful and important; but we cannot help bearing our teſtimony againſt his work, as tending to direct the labours of philological enquirers to wrong objects, and to withdraw their attention from thoſe ſources, whence Engliſh and all other European languages, ancient and modern, have ſprung. But let us hear his own words: "The bulk and foundation of the Latin language is Greek; but great part of the Latin is the language of our northern anceſtors grafted upon the Greek. And to our northern language the etymologiſt muſt go, for that part of the Latin which the Greek will not furniſh; and there, without any twiſting or turning, or ridiculous forcing and torturing of words, he will eaſily and clearly find it. We want, therefore, the teſtimony of no hiſtorians to conclude that the founders of the Roman ſtate and of the Latin tongue, came *not from Aſia, but from the north of Europe*. For the language cannot lie. And from the language of every nation we may with certainty collect its origin. In the ſame manner, even though no hiſtory of the fact had remained; and though another Virgil, and another Dionyſius, had again in verſe and proſe brought another Æneas from another Troy to ſettle modern Italy, after the deſtruction of the Roman government, yet, in ſpite of ſuch falſe hiſtory, we ſhould be able, from the modern language of the country, (which cannot poſſibly lie,) to conclude with certainty, that our northern anceſtors had again made another ſucceſsful irruption into Italy, and again grafted their own language upon the Latin, as before upon the Greek. For all the Italian which cannot be eaſily ſhewn to be Latin, can be eaſily ſhewn to be our northern language. Mr. Wakefield had, ſhortly before his death, agreed with me to undertake, in conjunction, a diviſion and ſeparation of the Latin tongue into two parts; placing together in one diviſion all that could be clearly ſhewn to be of northern extraction." (Vol. ii. p. 140.) In p. 299, he gives the following inſtances, with many others, of Latin words derived from the northern language:

Habian,	*habere*	Dilgian,	*delere*
Hnæcan,	*necare*	Malan,	*molere*
Higan,	*ire*	Erian,	*arare*
Hentan,	*hendere*	Tillian,	*tollere*
Wealopian,	*volvere*	Gnittan,	*nectere*
Fleuan,	*fluere*	Nigtan,	
Spiran,	*ſpirare*	Kerſan,	*creſcere*
Speowian,	*ſpuere*	Tekan,	*tangere*
Spitan,	*ſputare*	Deman,	*damnare*
Mileſcian,	*mulcere*	Profian,	*probare*
Meolgian,	*mulgere*	Reafian,	*rapere*
Pinan,	*punire*	Suegian,	*ſuadere*
Pyngan,	*pungere*	Biddan,	*petere.*
Fegan,	*figere*		

According to Mr. Tooke, the words in Roman letters are plainly of northern origin, while thoſe correſponding to them in italics are Latin verbs derived from them. The reverſe of this poſition we can prove to be true. The Anglo-Saxon, or Gothic words, which this author dignifies as northern primitives grafted on the Latin, are no other than Latin words borrowed and corrupted by the northern barbarians when they over-ran the Roman empire. This poſition, if proved, will render the far greater part of Mr. Tooke's labours perfectly nugatory; and nothing more is neceſſary to prove it than to ſhew that the originals of the Latin words exiſt in Greek, or in one of the Oriental tongues, and exiſt too in ſuch a form, as to evince that *theſe* are the primitives, and conſequently that the northern words are only corruptions derived from thence. Thus the Hebrew כף, *kaph*, is *a hand;* hence *capio*, to take in hand, and by ſoftening *c* into an aſpirate, as is often the caſe, *habeo*, to hold in the hand, *i. e.* to have. The Greek νικη, overthrow, is the parent of the Latin *neco*, corrupted into *hnæcan;* ειω, I go, *eo*, *higan;* χανδω, *hendo*, *hentan*, to ſeize; ειλεω, *volvo*, *wealopian*, to roll; φλυω, *fluo*, *fleuan*, to flow; שׂפ, *ſpu*, and שׂפת, *ſput*, ſignify *lips;* hence *ſpuo*, or *ſputo*, the action of the lips in throwing out of the mouth, *i. e. ſpue*, *ſpit;* μαλακιζω, to ſoften, *mulceo*, *mileſcian;* αμελγω, *mulgeo*, *meolgian*, to milk; ποινα, recompence, puniſhment, *punio*, *pinnan*, to puniſh; πυγη, a tail, *pungo*, *pyngan*, to act as a tail does, *i. e.* to prick; πηγω, *figo*, *fægan*, to fix; λουω, *leo*, *deleo*, to waſh down, to obliterate by waſhing, *dilgian;* μυλλω, molo, Goth. *malan*, to mill; Chaldean ארע, *aro*, αροω, aro, *erian*, to plow; τελλω, to riſe, tollo, *tilian;* νηθω, to ſpin, twiſt, *necto*, *gnittan*, or *nigtan;* θηγω, tego, or tango, *tekan*, to touch; δαμαω, *damno*, *deman;* φορβη, food, *probo*, to taſte food, *profian*, to prove; αρπαζω, tranſpoſing *r*, as is often the caſe, *rapio*, *reafian;* ποθεω, to deſire, *peto*, to ſeek in conſequence of deſiring, *biddan*.

Though this liſt clearly ſhews that the Northern language is, in a great degree, a corruption of the Latin borrowed from the Greek, the Hebrew, and other Oriental tongues, yet Mr. Tooke gives it as exhibiting inſtances of the Northern dialect grafted on the Latin. The primitive language of the North could have been no other than a branch of the primæval language of men, conveyed there by the firſt emigrants, diverſified and enriched by communications with the Eaſt on the north of Aſia, by early irruptions into Greece, as is mentioned by Herodotus, and, in far later days, by amalgating with the Latin, when in the dark ages the tribes of the North invaded and diſmembered the Roman empire. In this ſtate, the Northern language became the parent of the Engliſh; and though a multitude of its words, eſpecially monoſyllabic words, are, no doubt, immediately from the Anglo-Saxon and Gothic; yet few inſtances, we believe, can be produced, which may not be traced, by a competent etymologiſt, through the medium of thoſe corrupt changes, to their primordial purity in Italy, in Greece, and in the Eaſt, the ſole origin of language and literature. But Mr. Tooke reverſes this natural and neceſſary order; and, without the teſtimony of hiſtorians, without any documents of the language ſubſiſting in the North, antecedent to that which was ſpoken in the middle ages, he fixes on corruptions borrowed from the Latin, and holds them up as the origin whence Latin, Greek, and Engliſh have been derived. His theory, thus far, is ridiculous and miſchievous; ridiculous, becauſe it is a palpable error, profeſſing important diſcoveries; and miſchievous, becauſe, while it pretends to trace words to their genuine roots, ſtops up all the true ſources of information on the ſubject of language. As we have paſſed this cenſure on his ſyſtem, we feel ourſelves called upon to juſtify it by more numerous inſtances. And we think this the more neceſſary, as ſubſequent grammarians, and the public in general, ſeem willing to acquieſce in his poſitions as incontrovertibly juſt.

In doing this we ſhall adopt the words which preſent themſelves, without much ſelection, referring our readers to the page where they occur in his ſecond volume. It was impoſſible to err as to the derivation of *right* from *rectum;* but *ſomething ordered* is not the leading idea of the term, though Mr. Tooke employs many quarto pages in explaining it on this principle. The primary ſenſe of *right* is *ſtraight*, a relative term, denoting the means to an end. Thus, *virtue* is *right*, becauſe it is the ſhort or direct road to happineſs. That hand is *right*, which does its work in the *ſhorteſt* way. Property is *right*, becauſe it is the ſtraight road to the welfare of ſociety. In this ſenſe we may ſay of God, if we ſay it with reverence, that it is *right* in him, becauſe, when he has an end to anſwer, right means the ſtraight way to accompliſh it. "The *left-hand* is that which is *leaved*, or which we are taught to leave out of uſe on ſuch occaſion," p. 10. This appears to us nonſenſe. *Left* is the Greek λαιος, and Latin *lævus*, with *t*, the uſual termination of northern words. *Lex*, Fr. *loi*, and our *law*, is from *lego*, and means ſomething *read* or *dictated*, and not *ſomething placed*, p. 8. The Anglo-Saxon, *lecgan*, *ponere*, is but a corruption of *locare*, to place. *Juſtus*, indeed, means ſomething commanded, *juſſum*, from *jubeo*. But this laſt is the Hebrew גוב, *gob*, and the Arabic *jaab*, to anſwer or aſſent. Hence, in Latin, *jubere legem*, to enact a law, *i. e.* to allow it to paſs, and promiſe to obey it.

"*To cucol* is to do as the cuckow does," p. 21. Few people know how the cuckow does; but all know how *a cock* acts on ſuch occaſions. *Kokoraa* is an Eaſtern word, which, coming into Italy, gave birth to *cicurio*, to crow; and, changing *r* into the connate *l*, as is often the caſe, to *kokolaa*, which, in Celtic, is *kilog* and *kilogee*, to act as a cock does with a hen. This, we preſume, is the origin of *cuckold*. *Hen-pecked* is a figure of the ſame nature, and from the ſame ſource. "*Alert* is *all-erecta*," p. 24. No, we preſume it is *all-ert*, or *all-art*, *i. e. all active*. The word *art*, ſignifying ſkill, came to ſignify that diligence by which ſkill is attained. The oppoſite, which ſanctions this etymology, is *inert*, not active. *A knave*, *i. e.* a man cunningly ſkilful, came, by the ſame aſſociation, from *gnavus*, diligent. "*Laſh*, (French *laſche*) of a whip, *i. e.* that part of it which is *let looſe*," p. 32. Rather from λυγος, *an oſier*. The French *laſche*, or the Italian *laſciare*, is the Latin *laxare*, from λυγοω, to bend. *To bren*, or *to burn*, gave birth to *brand*, *i. e.* a mark by burning;—*brandy*, *i. e.* ſpirits which burn;—*brown*, *i. e.* bread burnt;—*brunt*, brunt of the battle, *i. e.* the heat of the battle, or the place where the battle burns. The origin is *furnus*, an oven. *Odd* is not the participle *owed*, *i. e.* ſomething owed to make up a pair, p. 38; but the Hebrew אחד, *ahad*, one, ſingle, ſingular, *i. e.* one that has no other to make an even number, or pair, with him. Thus we ſay, an *odd man*, *i. e.* a ſingular man. *Loud*, p. 39, is, we preſume, from κλυτος, a voice heard. The Anglo-Saxon, derived from this word, has preſerved the κ aſpirated, *hlowan*. In Celtic it is *cloed*, that which is heard in praiſe of a man. The Latin has rejected the guttural altogether in *laudo*. The Greek poets have applied the epithet κλυτος to ſuch animals as *bleat;* hence *low: ſhred*, or *ſherd*, *ſhur*, *ſhare*, (as plough ſhare) p. 41, come from κειρω, to clip, by prefixing *s*, a practice very frequent in Latin; and hence the Anglo-Saxon *ſcyran*, to ſheer.

One of thoſe broad analogies by which the Latin ſeparated from the Greek, is to convert a guttural into a labial, as in χλοη, *flos*, χλωρος, *floridus*. Thus it may be, *cultus* became, as it were, *fultus*, *fult*, *field*, *i. e.* a cultivated ground, and not *a place felled*, p. 41. *Coward* is the participle of *cower*, to bend; but the parent of this verb is *corruo*, to ſhrink, p. 42. *Bread* is beared, *i. e.* the produce of the earth, as *bearn*, offſpring, is *boren*, ſomething born, and not from the obſolete *bray*, to pound, which is taken from the Latin *frico* or *frango*; both of which originated in the Arabic פרק, *pharac*. *Fiend*, *foe*, is the participial termination of βια, or βιαζω, *violence*, in which, as Socrates ſays, there is *enmity*; while *friend* is the ſame form of *frau*, a woman, (from φερω *i. e.* the bearing animal,) and ſeems at firſt to mean a *female loved*. The letter *l*, being of the ſame organs with *n*, is often changed for it in all languages, as νυμφη, *lympha;* πνευμα, *pulmo*. On the ſame principle, the Hebrew נאף, *naaph*, *to marry*, became *laaf*, or *love*. The Hebrew חית, *hhit*, and the Perſian *hhod*, *ſelf*, paſſing to the North, gave birth to the pronoun *hit*, or, as it is farther corrupted, *it*, which, like *id* in Latin, directs the attention to ſomething going before, and is a ſubſtitute for it. Gothic *haitan*, Anglo-Saxon *hætan*, or *gætan*, to *ſpeak* or *command*, is, perhaps, the Greek αυδαω, which, in Celtic, is *gwyd*, in Engliſh *quoth*, and in Latin in the compound form of *in-quit*, p. 53.

Tight, *i. e.* tied, and the Gothic *tian*, is from πτυσσω, *to fold up*, 67. *Twiſt* is *tortus* or *toſtus*, and not that which is *twiced*. *Quilt* is *coiled*, (κυλιω,) twiſted. *Draught*, *drag*, is τρωχαω, *traho*. *Tilt* is *tilted*, lifted, from τελλω, *tollo*. "*Barren*, *i. e. barred*, cloſed, ſhut", p. 72. The verbs φερω, *fero*, *bear*, *paro*, *pareo*, *pario*, with the numerous tribes of words derived from theſe in all languages, owe their exiſtence to the Arabic *barron*, *the earth*, or that which produces all things: and *barren*, we preſume, meant primarily an animal having produced; and thence it denoted *infecundity*, conſequent on production, or, more generally, incapacity to produce. The Hebrew צר, *ſter*, denotes any thing *cloſe*, *ſharp*, or *hard*. Hence the Greek στερεος, *firm*, *rigid;* and our *ſtern*, p. 73. The ſame word in Arabic means a harſh or acute ſound, and hence ſeemingly the Engliſh *ſtir*. The Arabic שיר, *ſeer*, which we ſhould pronounce *ſteer*, denotes to flow, or to move as water does. Hence the Anglo-Saxon *ſtiran*, which means to cauſe a ſhip to move, which is the meaning of the hence-derived *ſteer*. *Stern* is that part of a ſhip which is thus moved. The Hebrew גור, *gur*, *to turn*, has given birth to *churn*, turning or ſtirring cream being the means of obtaining butter, which in Anglo-Saxon is *gyran*, 76; to *year*, which is a revolution of time; to *yarn*, which means therefore ſomething *turned* or *twiſted*, and not prepared. Πιλος, *pilus*, means hair on the head; hence it ſignified to form hair, or to grow into a head. And this is the origin of our words *pile*, *build*. *Bold* or *bald* originated in *validus*, bodily ſtrength naturally inſpiring mental energy, 79; but *bolt*, p. 128, is βελος or βλητος, the thing caſt, 129. *Boar* is the Hebrew בעיר, *bacer*, a ſturdy ſtupid animal; but *brawn* we think is not *baeren*, but *pork*, *porken*, *proken*, *brawn*, from *porcus*, and therefore it means the fleſh of a pig, 87.

Chop, *chip*, is ſomething cut off, from κοπτω. The Anglo-Saxon *plihtan*, to pledge, is from πλησσω or πληγω, *to ſtrike*, plight being a bargain ſtruck. *Shut* is the ſame in ſenſe and ſound with the Arabic שד, *ſhud*. The Anglo-Saxon *ſcitan* is nothing but the Hebrew שת, *ſhit*, *nates;* and hence it came to ſignify the action of the nates in throwing away the excrements. We ſhall merely add the following liſt, and all the words in the laboured chapter on *abſtraction* are, with few exceptions, capable of being traced in the ſame manner; and we deſire our readers to compare the derivations here given with thoſe of Mr. Tooke in the pages referred to.

Θρυλλεω, to divulge or expoſe; *trull*, a public woman, p. 153. Τρεπω, *to turn, drab,* a woman that turns about, a vagabond woman, 154: hence the Gothic *treiban,* to drive about, or turn out, 155. The Arabic עלף, *alph*, means *food, ſupport*, and hence *loaf,* the means of ſubſiſtence. The Anglo-Saxon has preſerved the naſal aſpirate *hlaf*, 157. From Λοφος, *a hill*, came the Anglo-Saxon *hliſian*, to raiſe to an high place; hence too *lofty, lift*, 162. רען, *rhen*, Anglo-Saxon *grenian*, vireſcere, *green.* Γηρασκω, Anglo-Saxon *geregnan*, to decay. *Grey*, 167, the colour of old age. שער, *ſhâr, ſhower.* שׂרה, *ſhire*, principality. *Shire, ſire, ſir.* *Ruga*, a wrinkle. *Rough*, Anglo-Saxon *rof*, 177. Υφω, *weave, woof,* Anglo-Saxon *wefan*, 178. Τασσω, *to arrange, bind, command*; hence *texo, to weave*; *tax,* tribute, *i. e. tag*, the thing faſtened, 179. Τελλω, to riſe; hence *tello, tall, i. e.* what is raiſed. Τελλω ſignifies alſo to command, and thence it came to denote voice, or ſound in general; *tell, tale, toll*, the ſound of a bell. Τελος, a tribute, *talio*, to pay, *toll.* Δουλευω, to ſlave, *to toil*, or, as it was formerly ſpelt, *tueil, ual; tool*, the medium of toil, an inſtrument. Hence, moreover, Anglo-Saxon *tillian, till, i. e.* to ſlave on the ground, cultivate the ground, 180. בר, *bar*, ſomething added on the outſide for the ſake of defence, is the origin of *bar:* בריה, *barvich*, is *burgh, borough*, a place barred, *i. e.* ſecured, which in Greek is πυργος, a tower, and in Engliſh *park:* moreover, the *bark* of a tree is ברק, *birk*, or that which ſeparates from the tree. The Arabic *borhaan, a nobleman*, is the parent of *baron*, and to this ſenſe of the word St. Paul alludes, in Acts, xvii. "the *Bereans* were more *noble* than thoſe of Theſſalonica." פלך, *phalk*, in Arabic means a *ſhip*, and this, by changing *l* into *r*, gave birth to *bark* and *barge*, 182. בור, *bur*, pit or grave, *bury*. Σωρος is *ſtore*, treaſure, 185. זרם, *ſtarm*, to inundate, is the Anglo-Saxon *ſtyrmian*, to rage as a flood, and hence *ſtorm*, 183. דא, *dana*, in Arabic means a body of people come together; hence *town*, 201. בית, *beet*, means *a houſe*, a place that holds or contains; hence *bed, abode, pot*, in Greek βαιτις, in Celtic *bedh*, the laſt abode of man, and *pit*. *Cauſo, to plead, to deliberate*, gave birth to *choice*, the effect of deliberation, and to *cozen, i. e.* to deceive by pleading. The Perſian *ſhiraab*, is vine, juice; and hence the Latin *ſorbeo*, and the Engliſh *ſyrup, ſhrub*, 209. מחר, *mehur, morrow*, Anglo-Saxon *mergen, morn*. Θερω, *to heat, to dry*, to evaporate by heat; hence Anglo-Saxon *drygan, drain*, 224. Ρηγος, *a garment, rug, rig.* Τρωχαω, *traho*, Anglo-Saxon *drag, dragen, drone*, an inſect that drags itſelf. שכל, *ſkal*, produced *ſkill*. The Anglo-Saxon *ſcylan*, to ſeparate, ſeems to have come from σκελος, *leg, i. e.* to put the legs in action, to ſeparate one from the other. *Scale*, to diſperſe, is σκυλλω, *jacto*; while *ſcale*, to weigh, is שקל, *ſhakl*, 233. Βρεχω, Βροχη, is *brook*. Φαυλος, *foul*, Anglo-Saxon *fylan, file, defile.* Γονυ, *genu, knee. Nuo, nutus, nod*, 254. Τελος, *talio, tole, dole, dollar, deal*, 256. לעג, χλευη, Anglo-Saxon *hlian*. Ταριχος, *ſalted curds, tart.* Στεγος, *a roof*, Anglo-Saxon *ſtigan*, to aſcend the *roof*. *Sty*, a place covered for hogs. *Stage*, a place covered for actors to entertain the people. Πλεω, *fluo*, by tranſpoſing *l*, is *full, fill.* Ferveo, *fretum*, the boiling ſea; hence *bruit*, noiſe of the boiling waves, and the Celtic *frood*, alſo *fret*. *Paſco*, to feed, Anglo-Saxon *byſcian*, to be occupied in feeding cattle, *buſy*. דין, *din, dun, dint*, 305. Κερμα, a ſmall piece, *crum*, Anglo-Saxon *grymman*, to prepare ſmall pieces by fire. *Dono*, to produce, yield, is the parent of *do*. דום, *dum; mute, dumb.* Μειρω, μορος, *mors*, Anglo-Saxon *myrran, mar.* שמד, *ſamad*, σμινθευς, *ſmite, ſmith, ſmitter*, 416. א־צ, *artz*, in Arabic *aarth, earth*, 417.

Theſe ſpecimens (and they are ample ſpecimens) will be ſufficient to enable us to form a juſt eſtimate of Mr. Tooke's merit as an etymologiſt. If the above are well founded, they ſhew that his labours have been greatly over-rated. His great error is, that by forced analogies, or rather contrary to all analogy, he has yoked together words as of a common origin, which have flowed from very different ſources; and this error has ariſen from his ſtudied inattention to the operations of the human mind, to his entire want of acquaintance with the Oriental tongues, whence all the European dialects, ancient and modern, have been derived; and to his prepoſterous attempt to deduce Engliſh, Latin, and Greek, from the corruptions of Latin and Greek by a barbarous people in the dark ages. Before we quit this ſubject, we ſhall make one or two obſervations worthy the attention of thoſe who trace the ramifications of modern languages from their ancient ſtems.

In the Oriental tongues gutturals abounded, which, like other conſonants, contained in themſelves the vowels neceſſary to their pronunciation. But it is the tendency of every guttural, when become habitual, to ſoften down, in the rapidity of utterance, into a mere aſpirate, till it at length vaniſhes. Thus *cornu* has degenerated into *horn*, and χωμος into *humus*, and into *homo*, a creature of earth; ſo in the Greek, the Oriental *khaan*, a king, became ανασσω, to reign, which Homer pronounced Φανασσω. This principle has obtained in the formation of many words, derived into Engliſh through the medium of the Anglo-Saxon and the Gothic. And the inſtances are ſtill more numerous where the aſpirate, inſtead of vaniſhing, has been converted into the labials *v, f,* or *y*. Thus *wicked* is the Arabic חקד, *haguad*; *warm*, the Perſian *garm*; *all*, ὁλος, *whole*, the Hebrew כל, *kal*; *work*, εργον, the Chaldean ארך, *aark*. חיל, *cheil, ſtrength*; hence *weal, wealth*, the ſtrength of a ſtate; *wall*, the ſtrength of a town; *heal, health*, the ſtrength of the human body. הרט, *hart, write*.

An inattention to this principle has betrayed Mr. Tooke into many errors; thus he derives *field* from *felled*, that is, a piece of ground in which the wood is felled; whereas we conceive it is a corruption of *cultus*; as if *fultus, fuld, field, i. e.* a cultivated piece of ground, preciſely in the ſame way as χλοη, became *flos*, and χολη, *fel, gall.* Ths ſubſtitution of the labial for a guttural or aſpirate obtained in an early period of the Greek, and conſtitutes the origin of what is called the *digamma*. This digamma prevailed in the age of Homer, when the language was chiefly oral. But his poems, as being written, preſerved the guttural or aſpirate, the true original character, which being ſtudied, cauſed the aſpirate to prevail in time over the digamma; and thus it reſtored the language to its primitive purity. But the Latin, having flowed from the Greek at an early age, when the caprice of oral ſounds ſpread uncontrolled by *written* letters, and having no monument of genius like the Iliad and Odyſſey to correct that caprice, as was the caſe in Greece, adopted the digamma, and thus ſeparated, by a broad line of diſtinction, from the parent tongue. We now return to the *properties* of nouns.

The properties of nouns are gender, number, and caſe. Gender, as meaning the diſtinction of ſex, was by no means a neceſſary property of nouns, for the ſignification was ſufficient to ſhew the ſex to which it belonged. Thus, as there were but two ſexes, there ſhould have been two genders, maſculine and feminine, nouns meaning males being ranked under the former claſs, thoſe meaning females under the latter; while the *neuter* or neither gender comprehended the names of inanimate things, or ſuch animals as had their ſex not diſcernible, or not neceſſary to be diſtinguiſhed. But unfortunately the termination of nouns became a mark of gender independent of their ſignification; and thus nouns were conſidered as maſculine, feminine, or neuter, as they happened to have the endings which cuſtom uſually aſſigned to either of theſe three claſſes. The Hebrew tongue, in its primitive purity, appears to have been exempt from this unhappy embarraſſment, and the only languages known to us which have maintained the empire of common ſenſe againſt the caprice of cuſtom are the Engliſh, the Perſian, and the Bengaleſe. In Greek and Latin the dictates of reaſon have ſo far prevailed as to cauſe all thoſe nouns, whatever be their terminations, which mean males and females, to be deemed maſculine and feminine; while the names of inanimate objects only are determined by the termination. In other languages, ſuch as the Arabic, French, and Italian, this abſurdity has been carried much farther, the names of inanimate objects being ſaid to have gender: the neuter, which is only the negative of ſex, is excluded; and the learner has his memory loaded with the gender of nouns which really meant things without ſex, and this without any one advantage to counterbalance ſo much fruitleſs trouble, and ſuch glaring ſacrifice of common ſenſe.

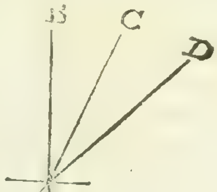
The Engliſh language, as conforming to nature in regard to the diſtinctions of gender, has greatly the advantage over other tongues: when riſing to the rhetorical and poetical ſtile it addreſſes the fancy by perſonification. This figure is eſſential to poetry. In order to intereſt the imagination, the ſubject of diſcourſe, when inanimate, muſt be inveſted with the forms and attributes of living beings. Now, when things are thus perſonified or ſpoken of as perſons, they muſt be repreſented as *male* or *female*. May they be made either? Or is there any analogy to give one the preference over the other? Let us hear what Mr. Harris (Herm. p. 44.) ſays on this ſubject. Having obſerved that ſome nouns are of ſuch a gender from having ſuch a termination, he thus proceeds: "In others we may imagine a more ſubtle kind of reaſoning, a reaſoning which diſcerns even in things without ſex a diſtant analogy to that great natural diſtinction which, according to Milton, animates the world. In this view we may conceive thoſe ſubſtantives to have been conſidered as *maſculine*, which were conſpicuous for the attributes of imparting or communicating, or which were by nature active, ſtrong, and efficacious, and that indiſcriminately whether to good or to ill, or which had claim to eminence either laudable or otherwiſe. The *feminine*, on the contrary, were ſuch as were conſpicuous for the attributes either of receiving, of containing, or of producing and bringing forth; or which had more of the paſſive in their nature than of the active; or which were peculiarly beautiful and amiable; or which had reſpect to ſuch exceſſes as were rather feminine than maſculine." On this principle the *ſun*, as imparting light, is maſculine; the *moon*, as receiving it, feminine. The *ſky*, or *ether*, *time*, *death*, the *ocean*, the *Supreme Being* are all maſculine; while the *earth*, *ſhip*, *city*, *virtue*, *religion*, are feminine. And yet Mr. Tooke roundly pronounces this reaſoning fallacious. "As for Mr. Harris's poetical authorities, the Muſes are bitter bad judges in matters of philoſophy. Beſides, that Reaſon is an arrant deſpot, who, in his own dominions, admits of no authority but his own. And he is particularly unfortunate in the very outſet: for his very firſt inſtances, the *ſun* and the *moon*, deſtroy the whole ſubtlety of this kind of reaſoning. For Mr. Harris ought to have known that in many Aſiatic languages, and in all the northern languages of this part of the globe which we inhabit, and particularly in our mother language, the Anglo-Saxon, *ſun* is feminine, and *moon* is maſculine," vol. i. p. 54. The author of the learned treatiſe on grammar in the Encyclop. Britannica, 17, reſting no doubt on the authority of Mr. Tooke, thus pronounces on the reaſoning of Mr. Harris; "Such ſpeculations are wholly fanciful; and the principle on which they proceed are overturned by an appeal to facts. Many of the ſubſtantives that in one language have maſculine names, have in others names that are feminine, which could not be the caſe, were this matter regulated by *reaſon* or *nature*."

The languages from which the objection to Mr. Harris's theory is derived are *not* regulated in regard to the diſtinction of gender by reaſon or nature. And facts borrowed from them are not ſurely to be admitted as concluſive againſt a principle in a language which *is* regulated by reaſon and nature. Mr. Harris deduced his theory from the Engliſh, though he has applied it with perhaps more fancy than truth to ſome inſtances in the claſſical languages. Our own tongue, as making all things neuter which have no life, admits the operation of fancy in perſonifying inanimate objects; and where perſonification is admitted, the *analogy* to the natural diſtinction of the ſexes muſt neceſſarily be admitted alſo. But, Mr. Tooke and his abettor ſay, it is *fanciful* becauſe it does not obtain in other tongues. Their argument is briefly this:—The ſun, by perſonification, is not made maſculine in Engliſh, where the conſideration of gender is founded on reaſon, becauſe it is made feminine in ſome languages where the termination, and not reaſon, determines the gender. Reaſoning of this kind is not only inconcluſive, but frivolous; and the analogy ſtated by Mr. Harris invariably and neceſſarily operates on our own tongue, and would have operated in *all* tongues, if, like the Engliſh, they had conformed to the ſtandard of nature; and we ought no more from their caprice to argue againſt the dictates of reaſon and analogy, than we ought to deny a regard to the diſtinction of ſex in the nouns of one language, becauſe the gender of the ſame nouns in others is regulated by conſiderations independent of ſex.

When a noun repreſents its object as *one*, it is ſaid to be in the *ſingular*, and *plural* when meaning more than one. This property alſo can hardly be ſaid to be neceſſary to nouns, as its place might have been ſupplied with greater accuracy by numerical adjectives when extended to expreſs numbers, as *two* men, *three* men, &c. "Bengal nouns," ſays Mr. Halhed, in his excellent grammar of that tongue, p. 68. "have neither dual nor plural numbers, I may add that neither is wanted. The *dual* is found in no modern language, and probably never exiſted but in the Arabic and its branches, in the Shanſcrit and in the Greek. That the idea of multitude is not confined to the plural number, is clear beyond a doubt, becauſe ſingular nouns are uſed in all languages with a collective ſenſe, almoſt as frequently as plurals, thus: *men love to ſtudy*, and *man loves to ſtudy*, are phraſes perfectly equivalent. So alſo we join to a noun in the ſingular number an epithet of indefinite plurality to convey a plural meaning: *many a man* is written by the Bengaleſe *bohoot manhooſh*. Perhaps it might be ſafely urged that the ſingular number has more occaſion for an accurate ſpecification than the plural; at leaſt this is the only circumſtance which can account for the extenſive uſe of the article or repreſentative of unity in moſt of the modern dialects of Europe."

The plural number in its origin was no other than a noun of multitude, annexed to that preceding it, in order to mark its extenſion from *one* to *many*. Thus in Hebrew, whoſe high antiquity unfolds to the philoſophical enquirer the ſeveral ſteps which mankind took in the formation of ſpeech: אנוש המון, *anoſh hemon*, a man multitude, became contracted, for the ſake of brevity, into אנושים, *anoſheem, men*. In the Chaldean and Syriac the final *m* was changed into *n*. Hence the Hebrew *eem* in Chaldean became *een*, in Arabic *oon*, in Perſian *aan*, to denote the names of animals, and *aa* inanimate things. And from this ſource are derived the plural terminations in *an* or *a* in the Anglo-Saxon and German tongues. The letters *n* and *s* being of the ſame organ, the Chaldean *een* became *ες* in the formation of the Greek, or *es* in the third declenſion of Latin nouns. Hence, too, the plural termination *s* in Engliſh and French; while the Italian excluſively follows the analogy of the ſecond Latin declenſion in *i*. Thus the plural termination in all languages, ancient and modern, appears to have been derived from one ſource: and that conſiſted of the annexation of a noun of multitude to the ſingular form of a preceding noun. And it is remarkable that in the Bengaleſe, which is but a branch of the Shanſcrit, this mode of expreſſing plural nouns is preſerved to this day; as, *projaa*, a peaſant, *projaa-lok*, peaſant-people, *projaalok*, peaſants; *lok* ſignifying people annexed to the ſingular noun whatever it might be. We ſhall only obſerve, that the names of claſſes only admit the plural form; while *proper* names in all languages are, by their ſignification, confined to the ſingular, unleſs many individuals by accident have the ſame name. The names of *families* and *nations* muſt likewiſe be excepted, which, from a regard to their ſignification, are neceſſarily *plural*.

We come next to the conſideration of *caſes*, which are properties of nouns, perplexed and undefined, as is evident from the different, and we may add, erroneous accounts given of them by moſt grammarians. The beſt and ſureſt way to aſcertain the nature and origin of caſes, is to attend to the manner in which they were at firſt conſidered in the Peripatetic ſchool. We adopt the words of Mr. Harris, p. 277. "The Peripatetics held the nominative to be no caſe, and likened the noun in this, its primary and original form, to a perpendicular line, ſuch for example as the line



A B. The variations from the nominative, they conſidered as if A B were to fall from its perpendicular, as for example to A C or A D. Hence, then, they only called theſe variations πτωσεις, *caſus, caſes*, or *fallings*. The Stoics, on the contrary, and the grammarians with them, made the nominative a caſe alſo. Words they conſidered (as it were) to fall from the mind, or diſcurſive faculty. Now, when a noun fell thence in its primary form, they then called it πτωσις ορθη, *caſus rectus*, an erect or upright caſe or falling, ſuch as A B, and by this name they diſtinguiſhed the nominative. When it fell from the mind under any of its variations, as for example in the form of a genitive, a dative, or the like, ſuch variations they called πτωσεις πλαγιαι, *caſus obliqui*, oblique caſes or ſide-long fallings, (ſuch as A C or A D), in oppoſition to the other (that is, A B), which was erect and perpendicular. Hence, too, grammarians called the method of enumerating the various caſes of a noun κλισις, *declination, a declenſion*, it being a ſort of progreſſive deſcent from the noun's upright form, through its various declining forms, that is, a deſcent from A B to A C, A D."

We copy this account becauſe it is very plauſible, though we regard it as erroneous; the learned author and Ammonius (De Interpret. p. 35.) from whom he derived it, being miſled by the figurative language borrowed from geometry. We believe that the nominative is ſaid to be in the right caſe, not becauſe it is an erect or upright falling from the mind, but becauſe the nominative, the verb, and its object following each other in direct ſucceſſion, form one ſimple propoſition. The nominative is the leading noun or *agent*, and the accuſative is the *effect*, in which the action ſtraightway terminates. And when other nouns are introduced, they are ſpoken of not directly as the agent or ſubject, but *collaterally* or *obliquely*, as objects to which the direct noun ſomeway belongs. Thus the accuſative as well as the nominative are right caſes, or direct parts of a propoſition; whereas the genitive, dative, ablative, and vocative are oblique caſes, or indirect parts of a propoſition.

From this ſimple ſtatement, which we recommend to our readers as important, we infer, that a caſe did not at firſt mean a *change* in the termination of a noun, but the *poſition* of a noun expreſſing its relation to ſome other word in the ſentence. And our next object is to aſcertain thoſe leading relations which the poſition of a noun, or ſome other means more ſpecific, expreſſes. *God made man* is a ſentence in which the agent, the action, and the object follow each other in the order of nature: *God*, as occupying the place of the agent, is the nominative; and *man*, as correſponding to the effect, is the accuſative. But in the ſentence *God is good*, we cannot ſay *God* is the agent, becauſe the verb *is* does not expreſs an action, but ſerves only to connect the epithet *good* with *God*. The nominative, therefore, here expreſſes not the agent, but the *ſubject* of the attribute connected to it. The nominative caſe, then, is that leading ſtate or poſition which expreſſes the *ſubject* of a connecting verb, and the agent of an active verb. And the accuſative is that poſition which expreſſes the effect of an active verb, and thus far ſimple poſition will carry us: and the nominative and accuſative have evidently to each other the relation which a cauſe has to its effect, and that for no other reaſon, but that their order correſponds to the order of cauſe and effect.

But ſuppoſe that my purpoſe was not only to expreſs a cauſe or agent, but the *origin* of that cauſe, or the *inſtrument* by which it acts, or the *end* for which it acts. In ſuch caſes ſimple poſition will be of no avail. I muſt have recourſe to ſome other expedient, and no expedient ſo well can ſerve as ſuitable words to expreſs origin, inſtrumentality, and end. "Thus, the *Son of God* redeemed mankind—he redeemed them *by his death*—he redeemed them *for happineſs*. In the firſt ſentence, *of* means beginning or origin; and *God*, ſucceeding it, as being the origin of *ſon*, is ſaid to be in the *genitive* caſe. In the ſecond, *by* denotes *inſtrumentality*, or medium; and as *death* is the inſtrument or medium by which Chriſt redeemed man, it is ſaid to be in the *ablative* caſe, and might more properly be ſaid to be in the *inſtrumental* or *medial* caſe. In the third inſtance *for* expreſſes the *end* for which Chriſt redeemed man: the noun happineſs ſucceeding it, is therefore in the *final caſe*, or as it is commonly, though unmeaningly, called the *dative* caſe."

The caſes, then, or thoſe leading poſitions of a noun that anſwer the purpoſes of ſpeech, are the nominative, accuſative, genitive, ablative, and dative. Let it be added, that the nominative, as it implies the name of its object, is often uſed merely to addreſs a perſon, and thus to fix his attention. In this ſtate the noun is ſaid to be in the *vocative* caſe, and is ſometimes preceded by the interjection O! But we have not yet done: the nominative and accuſative are expreſſed by poſition; while the oblique caſes, the genitive, ablative, and dative depend on words expreſſing beginning, medium, and end. Let us a little contemplate the conſequence of theſe words, or words of the ſame import, when firſt introduced into diſcourſe. As the relations of things are in the order of our ideas *conſequent* upon the things ſo related, prepoſitions denoting thoſe relations muſt at firſt have ſucceeded the nouns which they now precede and govern. Thus in the above inſtances, the order would have been *God of—death by—happineſs for*. And it is remarkable, that in the Hindooſtanic the prepoſitions to this day generally ſucceed the dependent nouns, inſtead of going before them, as in other tongues. The conſequence of this was, that the prepoſitions, abbreviated perhaps into ſingle letters, coaleſced with the preceding noun, forming thereby one word with it. Thus *godof, godby, godfor*: and the variety of terminations given by this means to the noun is the origin of caſes. Modern tongues, in rejecting this variety, and ſubſtituting prepoſitions, have only recurred to the original purity of language.

Grammarians have generally concurred in defining caſes to be changes of termination. In this, if the above account be juſt, they are miſtaken, not only becauſe *poſition* is the primary and eſſential idea of a caſe; but becauſe while they reject prepoſitions as marks of caſes, the caſes defined by them are no other than the prepoſitions which they reject. Conformably to this notion, they maintain that the Engliſh noun has no other than the poſſeſſive caſe: and Dr. Lowth and Mr. Lindley Murray, purſuing the ſame error to its conſequences, comprehend nouns expreſſing the relation of effect, the relation of beginning, the relation of medium, and the relation of end, under one unmeaning phraſe of *objective caſe*, thus confounding relations the moſt neceſſary to the purpoſes of ſpeech, the moſt diſtinct in themſelves, and moſt requiſite to be kept diſtinct in the mind.

The ideas of the moſt acute and learned grammarians have hitherto been confuſed and contradictory on the ſubject of caſes, eſpecially the oblique caſes. And the author of the treatiſe in the Encyclop. Britannica has juſt left the matter obſcure and uncertain, as he found it. "The genitive, ſays he, is the moſt general of all the caſes, and gives notice that ſome connection indeed ſubſiſts between two objects, but does not point out the particular kind of connection. *That* we muſt infer, not from the nature or termination of the genitive itſelf, but from our previous knowledge of the objects connected. That the genitive denotes merely relation in general, might be proved by adducing innumerable examples, in which the relations expreſſed by this caſe are different." Theſe obſervations clearly ſhew that this writer did not himſelf underſtand the meaning of the genitive caſe, which, inſtead of expreſſing *ſome connection* between two objects, or *mere relation in general*, uniformly expreſſes one and the ſame relation, namely, that of *beginning*, *ſource*, and *origin;* and *of*, the mark of it, has uniformly the ſame ſenſe with *from*. Thus a table *of* wood, a table *from* wood; wood being the origin of the table. Rays *of* the ſun, rays *from* the ſun, the ſun being the origin of the rays. And *beginning* will appear to be the primary idea implied in *of*, if we trace it to its origin; *of, ab, απο*, אב, *ab, parent, ſtem, root*. Thus alſo in Latin *Dei gratia*, the grace of God, the grace from God, the grace of which God is the ſource. Of the phraſe *injuria regis* the writer ſays, no man can know whether the injury mentioned be an injury *ſuffered*, or an injury *inflicted* by the king. We deny this: if the terms be uſed in ſtrict propriety they muſt mean an injury from the king, an injury of which the king is the ſource and author; and, if they are intended to denote an injury received by him, the expreſſion is incorrect and ambiguous, though the ambiguity would be removed by the context: and this leads me to remark, that as the beginning of a thing is the *author* of it; and as the author has a full right to the fruits of his labours, ſo that ſtate of the noun which expreſſes beginning came to ſignify the *owner* or *poſſeſſor*. And thus the genitive in Greek and Latin expreſſes the relation of poſſeſſion, and anſwers to what is called in Engliſh the *poſſeſſive* caſe. Thus, *my father's will* may mean the will of which my father is owner; it means alſo the will which originated in my father. The poſſeſſive caſe, in our tongue, is an evident abbreviation of the genitive termination of the third declenſion in Latin, *father is houſe, father's houſe*, the apoſtrophe above ſupplying the place of the excluded vowel.

The ſame writer has not defined the meaning of the *dative*, though the relation denoted by it is the moſt obvious of any, contenting himſelf with ſaying, that it has nearly the ſame ſenſe with the accuſative, 19. No two relations, however, can be more diſtinct; as the accuſative expreſſes the effect of an action, and therefore ſtands immediately connected with that action; whereas the dative denotes the *end* to which a motion or action tends, and in which it terminates, or the point to which the attention is directed forward, as that to which ſomething elſe is related. Thus, in the inſtance given by him, *comparo Virgilium Homero*. The immediate object of compariſon is *Virgil*, and *Homer* is the point, or ſtandard placed before me in making that compariſon. The two firſt words expreſs the action and its effect, the laſt holds to view the point to which they are directed. It is true that in this and ſimilar inſtances, the mind brings under one view the perſon compared and the perſon to whom the compariſon is made; and this proximity or juxtapoſition conſtitutes the affinity which the writer erroneouſly ſuppoſes to be between the two caſes. *Antonius læſit Ciceronem*, and *Antonius nocuit Ciceroni*, he farther ſuppoſes to be expreſſions of the ſame import; but in this he has been miſled by the genius of our tongue, which would expreſs each phraſe by *Antony hurt Cicero*. But this is the exact meaning of the firſt clauſe only. In the ſecond clauſe *nocuit* expreſſes not an *action*, but aſſerts a *quality*. Antony was hurtful to Cicero. Antony was hurtful, and Cicero was a perſon to whom his hurtful behaviour was directed.

The dative caſe ſtands oppoſed to the genitive as *end* to *beginning*. The latter is the point where motion *begins*, the former where it *terminates*, and the ablative is the medium or inſtrument between both. In conſequence of this connection between the ablative and the genitive, on one hand, it came in Latin, by the mere impulſe of repeated aſſociations, to mean in many inſtances the ſame relation with the genitive, and this is the reaſon why the ſame word often governs a genitive or an ablative, why in our own tongue *of* and *from* have preciſely the ſame ſignification, and why the French and Italian expreſs the genitive by thoſe prepoſitions which in Latin govern the ablative. On the other hand, as the inſtrument or medium is connected with the end, the ablative holds a ſimilar connection with the dative. Hence in Latin theſe two caſes are often uſed one for the other, which is certainly a great impropriety in that language, and which occaſions much perplexity to the learner; while in Greek, which has not a diſtinct ablative, the relations of inſtrumentality and end are expreſſed by the ſame termination, which is certainly a great defect in that elegant and copious language. Inſtrumentality implies *concomitancy;* but this is not the primary ſenſe of the ablative, as the author of the above treatiſe erroneouſly ſuppoſes.

The Origin and Properties of Adjectives.

Things or ſubſtances are known and valuable on account of their qualities; the qualities of things therefore firſt engaged the attention of mankind. And as they perceived that the ſame quality exiſted in the ſame or in a different degree, in different things, men, however rude or uninformed, learned to form ideas of qualities independent of the ſubſtances to which they belonged. Hence they acquired that claſs of words called *adjectives*, which are only the names of qualities. Now as qualities reſult from things, the names of qualities are derived from the names of things; and, as moreover qualities are conſtant concomitants of the things they characterize, the names of qualities are conſtant adjuncts of ſubſtantives expreſſed or implied. Hence they are ſometimes called *nouns*, becauſe they have been borrowed from nouns; and always called *adjectives*, becauſe they are always *adjected* or *added* to nouns, and for this reaſon they have alſo the name of *adnouns*. From this account of adjectives we deduce the following inferences, which are worthy of attention.

Firſt, adjectives expreſſing the ſimple qualities of natural objects, which do not imply *motion* or *action*, are derived from nouns, by the mind firſt abſtracting the quality from the thing it qualifies, and then generalizing it ſo as to make it an epithet expreſſive of a ſimilar quality in different things. Thus in πρηων, *a ſteep rock*, the quality *ſteep*, contemplated firſt as a quality of that particular thing, the mind ſoon learned to conſider as *ſeparate* from the rock, and hence to make it a general term of the like quality in other objects. Thus was derived the adjective πρηνης, *pronus*, prone. And in the manner this ſingle adjective is formed, are formed all the adjectives which exiſt in all languages.

When adjectives became numerous in any language, analogy or cuſtom ſoon aſſigned them a particular termination. Hence, on every converſion of a noun into an adjective, that adjective immediately aſſumed the ending which analogy had appropriated to words of that claſs. Thus φορβα, *food, reliſh*, was changed into *probus*, ſignifying agreeable food or wholeſome reliſh. Thus alſo *wood*, *wind*, became *wooden*, *windy*, in our own tongue. It is obvious from this to obſerve, that in the earlier periods of human language, adjectives approached nearer in meaning and termination to the nouns whence they were derived; that is, they were leſs abſtracted and generalized. But the principles of abſtraction and generalization were greatly facilitated, when a quality was once expreſſed by an independent word; the eyes and the ears being made by that means to aid the conceptions of the mind. This is the reaſon why a barbarous people have few or no adjectives; and why, in the more ancient dialects of the Eaſt, the uſe of adjectives is far leſs frequent than in the more recent languages of Europe.

In ſpeaking of the qualities of things, *ſimilitude* or *reſemblance* is an idea of high importance and frequent recurrence. A perſon diſcourſing to another of ſomething *unknown*, naturally ſays, that it is *like* to ſome other that *is* known. Thus in Greek εικος, *image;* ειδος, *form;* ιος, *like;* are combined with nouns in order to expreſs *likeneſs*; ανθρωπικος, *man-like*; Εκτορειδης, *having the form of Hector*, *Hector-like*, i. e. *the ſon of Hector;* ανθρωπειος, *man-like.* This laſt termination, by inſerting *s*, gave birth to the Latin adjectives in *oſus*, and to our adjectives in *ous; pecunia*, *pecunioſus; glory*, *glorious.* The numerous adjectives and adverbs in Engliſh are formed on the ſame principle. *Earthly*, i. e. earth-like, which is the Greek διγκιος. *Gladſome* is *gladſame*, the *ſame* with glad; *ſome* or *ſame* being, we conceive, corruptions of *ſimilis*. The termination *iſh* is originally the Perſian *waſh*, added to a noun to expreſs likeneſs; as *gomer, the moon; gomer-waſh, mooniſh, like the moon; womaniſh, like a woman.* The termination *en*, derived, it is allowed, from the northern language, is borrowed by that language from the Greek participle in *on*. In the ſame manner we form ſome adjectives after the analogy of the paſt participles in *ed*, as *honied*, *wooded*; while that of *y* is the Anglo-Saxon *ig*; but this is only the Latin termination *cus*; as *unicus*, Anglo-Saxon *anig*, *any*.

But it muſt not be omitted that a very numerous claſs of adjectives is derived from *verbs*, and that independently of participles. Of this origin are all thoſe adjectives whoſe qualities pre-ſuppoſe *motion* or *action;* and they imply greater power of abſtraction than thoſe derived from nouns. Mr. Tooke, indeed, denies this power as a principle influencing language; and by this rejection is led to deny the exiſtence of adjectives as a claſs diſtinct from nouns. His definition is the following. "An adjective is *the name of a thing*, which is directed to be joined to ſome other name of a thing." (Vol. ii. p. 241.)

As his authority on the ſubject of language is ſo high in the eſtimation of many, we ſhall briefly examine and refute the above definition. His arguments are theſe; "I think you will not deny that *gold* and *braſs* and *ſilk* is each of them the name of a thing, and denotes a ſubſtance. If then I ſay a gold-ring, a braſs-tube, a ſilk-ſtring, here are the *ſubſtantives* uſed adjectively, yet names of things, and denoting ſubſtances. If again I ſay a golden ring, a brazen tube, a ſilken ſtring, do gold and braſs and ſilk ceaſe to be the names of things, and ceaſe to denote ſubſtances, becauſe, inſtead of coupling them with ring, tube, and ſtring by a hyphen thus (-), I couple them to the ſame words by adding the termination *en* to each of them? Do not the adjectives which I have made ſuch by the added termination *golden*, *brazen*, *ſilken* convey to the hearer's mind, and denote the ſame things as gold, braſs, and ſilk? Surely the termination *en* takes nothing away from the ſubſtantives gold, braſs, and ſilk, to which it is united as a termination: and as ſurely adds nothing to their ſignification, but this ſingle circumſtance, *viz.* that gold, braſs, and ſilk are deſignated by this termination *en* to be joined to ſome other ſubſtantive;" p. 430. Again he ſays, p. 442, "But if, indeed, it were true that adjectives were not the names of things, there could be no attribution by adjectives; for you cannot *attribute nothing*. How much more comprehenſive could any term be by the attribution to it of *nothing?* Adjectives therefore, as well as ſubſtantives, muſt equally denote ſubſtances; and ſubſtance is attributed to ſubſtance by the *adjective* contrivance." He concludes with what Dr. Jonathan Edwards ſays of the language of the Muhhekanew Indians. "The Mohegans have no adjectives in all their language, although it may at firſt ſeem not only ſingular and curious, but impoſſible that a language ſhould exiſt without adjectives, yet it is an indubitable fact."

This account, inſtead of unfolding that ſimplicity and preciſion which mark the proceſs of the human mind in the formation of language, tends to eraſe the very elements of knowledge, and to confound ideas the moſt palpable and diſtinct. Our ideas naturally and obviouſly divide into two claſſes, ideas of qualities and ideas of things. The diſtinction between theſe claſſes is univerſal; it is common to the philoſopher and the bulk of mankind; and is moſt readily comprehended even by children. As we have then *ideas* of qualities, language muſt have *words* to expreſs thoſe qualities, *i. e.* it muſt have *adjectives*; and as our ideas of qualities are in their nature diſtinct from, though concomitant ideas of things; ſo adjectives muſt in their nature be diſtinct from, though adjuncts of nouns.

The firſt ſtep in the formation of adjectives is *abſtraction*; the mind being led to conceive of the quality independent of the thing, in conſequence of perceiving it in *different* things. The frequent recurrence of the quality, which is one and the ſame, and therefore remembered, while the ſubſtances which preſent it are numerous and ſucceſſive, and therefore forgotten, greatly facilitates our abſtract conceptions. A ſimilar facility, as we have already obſerved, is afforded by the independent uſe of words to expreſs qualities. The dependence of adjectives on the principle of abſtraction is evident from one circumſtance. *Like* is a very abſtract quality; and the union of this word with nouns is one copious ſource of adjectives in moſt languages of which we have any knowledge.

The next ſtep in the formation of adjectives is *aſſociation*. This principle is ſo powerful and inſtantaneous, that it changes the nature of a word, in conſequence of its connection with other words, and of our previous experience. Thus, "the ladies *fan* themſelves"—"The plumy people *eye* the falling verdure." Becauſe we have experienced the middle term of a ſimple direct propoſition to be always a *verb*, we inſtantly, in the above examples, conclude that *fan* and *eye* do not here denote the things uſually meant by them, but the *operations* of thoſe things; that is, aſſociation and experience convert the nouns *fan* and *eye* into verbs, without any thing to aid or indicate that converſion but aſſociation ſuggeſted by the collocation. This converſion of a noun into a verb by ſimple experience, illuſtrates the converſion of a noun into an adjective. We place a word ſignifying a quality before a word denoting a ſubſtance; and as we uniformly find that qualities belong to the things which they qualify, and firſt act upon our perceptions, we inſtantly infer from the collocation that the firſt expreſſes an attribute of the ſecond; and this attribution is not indicated by the termination of the attributive, but an *inference* of the mind founded on experience. The termination *en* ſignifying *to be added* is a conceit of this grammarian, and has no foundation in truth: for it is the Greek participial termination in *on*, borrowed by the Goths. The formation of language did not require ſuch petty, circuitous contrivances; but points to the broad and ſimple principles of abſtraction and aſſociation as the copious ſources of all its phenomena.

From this it appears, that a peculiarity of termination is not neceſſary to form an adjective, the collocation being ſufficient to aſcertain its character as ſuch. An adjective may have the ſame ending with any other noun, or with the very noun from which it was derived; and it has this identity of termination in Greek and Latin, and yet no ambiguity ariſes as to its nature and uſe. The inference, which we inſtantly, and we may ſay, imperceptibly, draw from the *juxtapoſition* in our own tongue, and from the ſimilarity of terminations in the claſſical tongues, is an unerring guide in theſe reſpects. And this is the reaſon why, in a barbarous language, it is poſſible that the name of a quality may be always the ſame with the name of the thing to which that quality belongs, and yet abound with adjectives, *i. e.* abound with nouns converted into adjectives by juxtapoſition. And this is all that can be meant by the teſtimony of Dr. Edwards, in regard to the language of the Mohegans. If there exiſted a language which had no verbs, but nouns converted (as in the above inſtance of *fan* and *eye*) into verbs without any variation of termination, a perſon who did not underſtand the nature of the human mind, and who had been accuſtomed to claſſify words only by their endings, might ſay of that language, that it had *no verbs*.

The foundation of Mr. Tooke's error, is the circumſtance that moſt adjectives were originally nouns. As they were nouns *in their origin*, and as he rejected the operations of the mind in the conſtruction of language, he inferred with confidence, that they were nouns *ſtill*, thus confounding in one promiſcuous maſs our ideas of qualities, and our ideas of things; yet, notwithſtanding this confuſion, he writes thus: "If in what I have ſaid of the adjective, I have expreſſed myſelf clearly and ſatisfactorily; you will eaſily obſerve that adjectives, though convenient abbreviations, are not *neceſſary* to language; and, therefore, are not ranked by me amongſt the parts of ſpeech; and, perhaps you will perceive, in the miſapprehenſion of this uſeful and ſimple contrivance of language, one of the foundations of thoſe heaps of falſe philoſophy and obſcure (becauſe miſtaken) metaphyſic with which we have been bewildered."

Adjectives, as expreſſing not things, but their qualities, cannot, in ſtrict propriety, have any *gender*; but, as in Greek and Latin, they have the ſame terminations with nouns, they are ſaid to be maſculine, feminine, or neuter, merely as they have maſculine, feminine, or neuter terminations.

In moſt languages, adjectives vary their endings to correſpond with the plural form of nouns; in Engliſh they have no ſuch variation, nor is it neceſſary, ſince qualities are not ſuſceptible of numerical diſtinction, being the ſame, whether applied to one or to many.

There is, however, one variation which adjectives have in all languages, namely, the variation to expreſs the three degrees of compariſon. The qualities of things differ in different objects, and they muſt be expreſſed with *augmentation* or *diminution*, as they are compared with others more or leſs intenſe.

When a quality is expreſſed without reference to any other, the adjective is then ſaid to be in the *poſitive* degree. When expreſſed with reference to the ſame quality or to another more or leſs intenſe, it is ſaid to be in the *comparative* degree; and when in the higheſt or loweſt degree of all, it is in the *ſuperlative*. Different languages have different ways of forming the comparative and ſuperlative; but in almoſt all, both theſe degrees are derived by certain ſyllables added to the poſitive: the adjective itſelf, by being thus *lengthened*, is made to correſpond with the augmentation in ſenſe, which the quality acquires by compariſon. The mode of expreſſing the degrees of qualities being only *two*, and therefore very general and imperfect, while the qualities themſelves vary in endleſs gradations, a more adequate method is uſed, by having recourſe to thoſe attributes of an inferior order, called *adverbs*, as *much good*, *tolerably good*, *exceedingly good*, *more good*, *moſt good*.

As it is not our object to detail the minute rules of grammar in our own tongue, we ſhall conclude this part of the ſubject with one or two obſervations on the three degrees of compariſon. The poſitive degree, though not implying an immediate compariſon with the ſame quality in a higher or lower degree, often conveys a *relative* or *comparative* idea; and for this reaſon may, by the aſſiſtance of a prepoſition, be made to expreſs the comparative or ſuperlative degree, as "Bleſſed among women, *i. e.* the moſt bleſſed of women." And this relative or comparative idea, implied in the poſitive, is the reaſon why the poſitive has ſometimes after it the caſe which is uſed after the comparative. On the other hand, the comparative and ſuperlative are uſed in a poſitive ſenſe, or uſed to expreſs a high degree without any immediate object of compariſon. Thus Virgil ſpeaks of Venus: "Triſtior et lacrymis oculos ſuffuſa nitentes."—*Triſtior*, more ſad than uſual, *i. e.* very ſad. This is more uſual in the ſuperlative degree, *vir doctiſſimus, a very learned man.* The comparative is uſed with propriety only when *two* things are compared;

the ſuperlative when a thing is compared with *many*. The elder of the two—the eldeſt of all. Nevertheleſs it is to be allowed, that multitude may be the object of the comparative, if preceded by *all* or *whole*, to give it a collective idea; as, "he is wiſer than all his teachers, *i. e.* he is wiſer than the whole body of his teachers,—he is wiſer than them all put together;—or, compared with his teachers one after another, he is wiſer than them all."

The Origin and Properties of Pronouns and Definitives.

Pronouns have been defined ſubſtitutes for nouns, to prevent their too frequent recurrence. Mr. Harris accounts for pronouns, or, as he calls them, *nouns of the ſecond order*, in a different way; and, as his explanation is curious, we ſhall here place it before our readers. "All converſation paſſes between individuals, who will often happen to be till that inſtant unacquainted with each other. What then is to be done? How ſhall the ſpeaker addreſs the other, when he knows not his name? or how explain himſelf by his own name, of which the other is wholly ignorant? Nouns, as they have been deſcribed, cannot anſwer this purpoſe. The firſt expedient on this occaſion, ſeems to have been *pointing* or *indicating* with the finger or hand; ſome traces of which are ſtill to be obſerved, as a part of that action which naturally attends our ſpeaking. But the authors of language were not content with this: they invented a race of words to ſupply this pointing, which words, as they always ſtood for ſubſtantives or nouns, were characteriſed by the name of *pronouns*. Theſe, alſo, they diſtinguiſhed into three ſeveral ſorts, calling them pronouns of the firſt, the ſecond, and the third perſon, with a view to certain diſtinctions, which may be explained as follows.

"Suppoſe the parties converſing to be wholly unacquainted, neither name nor countenance on either ſide known, and the ſubject of converſation to be the ſpeaker himſelf. Here, to ſupply the place of pointing, by a word of equal power, the inventors of language furniſhed the ſpeaker with the pronoun I; *I write, I ſay, I deſire*, &c.; and as the ſpeaker is always principal with reſpect to his own diſcourſe, this they called, for that reaſon, the pronoun of the firſt perſon. Again, ſuppoſe the ſubject of the converſation to be the party addreſſed. Here, for ſimilar reaſon, they invented the pronoun *thou*; *thou* writeſt, *thou* walkeſt, &c.; and, as the party addreſſed is next in dignity to the ſpeaker, or at leaſt comes next with reference to the diſcourſe, this pronoun they therefore called the pronoun of the ſecond perſon.

"Laſtly, ſuppoſe the ſubject of converſation neither the ſpeaker nor the party addreſſed, but ſome third object different from both. Here they provided another pronoun, *he, ſhe, it*, which, in diſtinction to the two former, was called the pronoun of the third perſon. And thus it was, that the pronouns came to be diſtinguiſhed by their reſpective perſons."

This account, which the author, as he ſays, received from Apollonius, is arbitrary and erroneous. The uſe of the pronouns is not to ſupply the names of perſons unknown to each other; nor can they be ſaid to have been *invented*: for though they anſwer the moſt uſeful purpoſes, they originated in circumſtances in which *deſign* had no concern. The origin of the two firſt pronouns we conceive to be this. They are the adjectives *one, two*, loſing their numeral ſignification, and coming to mean the ſpeaker and the perſon addreſſed, by the mere force of aſſociation with the verb. Let us ſuppoſe that a perſon wiſhed, in the infancy of language, to expreſs the propoſition *I love thee*. If Engliſh were his words, he would have ſaid, *one love two*. This form being repeatedly uſed, and the perſon uſing it accompanying the leading term *one* with a conſciouſneſs of himſelf, that term would gradually drop its character of one in oppoſition to *two*, and derive a new character by aſſociation from the verb, namely, one that was ſpeaking in oppoſition to the other ſpoken to. Thus the ſame proceſs which converted *one* in general into *one ſpeaking*, converted *two* into the perſon addreſſed.

That the pronouns *I, thou*, were originally *one, two*, will appear probable from hence. In Hebrew, the moſt ancient language, the pronoun anſwering to *I* is evidently the parent of the numeral *one*; and *two* has a cloſe reſemblance to *thou*. Thus אני, *ani*, ego, is ἓν in Greek, and *unus* in Latin, and the other form אנכי, *anki*, is *unicus*. Moreover, אתה, *ato*, by dropping א ſeems to have produced τυ, *tu, thou*: and δυο, *duo, two*. And in other tongues the pronoun *thou* and the numeral *two* have ſuch reſemblance as to beſpeak one common origin in Hebrew. Beſides, the pronouns *I* and *thou* ſtill retain their origin in their names; *I* being the *firſt* perſon, *thou* the *ſecond*; not becauſe the former is the firſt and the latter the ſecond in dignity, but becauſe theſe were their original meaning. Moreover, the numerals *one, two*, muſt have been among the firſt adjectives formed by abſtraction from ſuch things as nature produced in pairs, or thoſe which alternately ſucceed each other, ſuch as *day* and *night*. And as diſcourſe is but an *alternation* or *interchange* of ſentiments between *two* perſons, the numeral adjectives in queſtion were the moſt likely to be uſed on ſuch occaſions. Remains of this uſage may be ſtill traced in ſome languages, as we ſay, *One thinks ſo*, or in French, *On dit*; *one* being not as Condillac (ſee his Works, tom. v. p. 184.) aſſerts, a corruption from *homme*, but of the Latin *unus*, and is not a ſubſtantive, but a ſubſtitute for a ſubſtantive, *i. e.* a pronoun. Finally, we obſerve that no words but *numerals* were capable of being formed by aſſociation into pronouns. The ſpeaker, indeed, might uſe his own name, and which, when repeatedly uſed, the verb would convert into the firſt perſon. But on the ſame principle another would employ his own name, and thus the aſſociations of one man would counteract the aſſociations of another; and neither name would be received as the repreſentative of the ſpeaker.

From this ſtatement of the origin of the pronoun, ſome particulars reſpecting its nature and uſe may be deduced with preciſion. Firſt, the adjective, in being changed into a pronoun, loſes the generality of a numeral, and aſſumes an individual character; that is, the character aſſigned to it by the verb. But as any other perſon may uſe that term in ſimilar circumſtances, the pronoun *I*, which was changed into the index of an individual by aſſociation, becomes again *general* by ſucceſſion; each ſpeaker having a right in his turn to uſe it: and thus the pronouns *I* and *thou* became ſubſtitutes for the names of all perſons in a change of ſituation. Secondly, *I* and *thou* are not, as has been ſuppoſed, ſubſtitutes for the names of the ſpeaker and the perſon addreſſed, to avoid their too frequent repetition, nor yet ſubſtitutes for thoſe names while yet unknown, but repreſentatives of thoſe perſons in that limited or reſtricted character which they derive from the aſſociated verb. Now as *ſpeakers* there is no difference between a man and a woman. A man that ſpeaks and the woman that ſpeaks, in that particular function, is the ſame: and the ſame thing holds in regard to the perſon addreſſed. The firſt and ſecond perſons, therefore, have not, in any language, the diſtinction of gender merely; becauſe they repreſent human beings in that particular character which excludes the idea of ſex. Thirdly, there is, properly ſpeaking, no ſuch thing as a *third* perſon; this being a *definitive*, marking the ſubject of diſcourſe, and ſaid to be the third perſon in reference to the *firſt* and *ſecond*, and thus repreſented as ſomething diſtinct from them, and not included under them. Thus הוא, *hoa*, in Hebrew, and *he* in Engliſh, were, as we ſhall preſently ſee, but the article; and ſo ὁ, ὁυτος, εκεινος, αυτος in Greek, and *hic*, *ille*, *is*, *ipſe*, in Latin, are all a ſpecies of reſtrictive or definitive adjectives, agreeing with the defined noun expreſſed or implied. As the firſt and ſecond perſons repreſent two individuals in peculiar circumſtances, they comprehend no other noun under them; whereas the third perſon is only in general a ſubject of diſcourſe, and therefore it comprehends any noun in the language, excepting the firſt and ſecond: accordingly every ſubject or agent in every language is the third perſon ſingular and plural, except four, *I*, *thou*, *we*, and *ye*, or their equivalents. The firſt and ſecond perſon, we have ſeen, exclude the idea of ſex, whereas it is a character often neceſſary to be marked in the ſubject or agent: for this reaſon pronouns of the third perſon have the triple diſtinction of maſculine, feminine, and neuter.

All the three perſons admit the plural number, as each is capable of repreſenting numbers. In our own tongue *I*, *we*, *thou*, *you* or *ye*; *he*, *ſhe*, *it*, *they*. Here it may be obſerved that *ye* is a corruption of *you* or *you* abbreviated; and as this abbreviation naturally takes place in the nominative or vocative, when the perſons addreſſed are called; and as it is neceſſary to be diſtinct when expreſſing the addreſſed perſons as affected by a verb, *ye* is uſed with propriety only in the nominative or vocative, and *you* in the accuſative. Men of rank being uſually ſurrounded with attendants, it became a compliment to addreſs a perſon as ſuch; in the ſame manner as in Greek, οἱ περι Πριαμον, *thoſe around Priam*, was a reſpectful way of deſignating Priam. Hence in common diſcourſe we uſe *you* for *thou*; and on ſuch occaſions the verb alſo ſhould be in the plural; as *you were* and not *you was*. But this complimentary ſtyle is not applied to the Supreme Being, who is always addreſſed by *thou*, from a regard, probably, to his *unity*, numbers being not able to add to his dignity or greatneſs. The regal ſtyle *we* has reſpect to the king's counſellors, who are ſuppoſed to adviſe the ſubject of diſcourſe, and who are reſponſible for it. With regard to the third perſon, though it be convenient to mark the gender, it is not eſſential: for the plural *they* is made to repreſent men, women, and things, without any inconvenience or ambiguity.

The perſonal pronouns, contrary to the analogy of nouns, have each three terminations, or three variations, to denote caſes. This is owing to their being derived from the Greek and Latin, with their reſpective inflexions. Their genitive, dropping the primary ſenſe of *beginning*, has uniformly the ſecondary ſenſe of *poſſeſſion*. Hence it is called, in our tongue, not improperly, the *poſſeſſive caſe*.

In Hebrew, Arabic, and Perſian, the perſonal pronouns are converted into adjectives, by being annexed to nouns, which, from their poſition, are called *affixes*. In this ſtate they are ſomewhat abbreviated and changed: but however changed when connected with nouns, they are always adjectives, but retain their perſonality when affixed to verbs. In our own tongue the perſonal pronouns are changed into adjectives from the genitive or poſſeſſive caſe: as *mine*, *my*; *thine*, *thy*; *hers*, *ours*, *yours*, *theirs*; *her*, *our*, *your*, *their*. Thus formed, they are properly called *pronominal adjectives*—adjectives, as qualifying nouns, and pronominal, as derived from the perſonal pronouns. *His* muſt be conſidered, by coaleſcence, as an adjective of this kind, through the genitive *he's*. Theſe pronominal adjectives, as derived from the genitive, may be reſolved into the ſignification of that caſe: as *my* of *me*; *thy* of *thee*; *his* of *him*, though ſeldom in Engliſh uſed in their perſonal form. The reaſon is, that our tongue has a ſtrong propenſity to convert nouns into adjectives by juxtapoſition, and thus to uſe them for the ſake of brevity, inſtead of the genitive: as when we ſay *ſilk-ſtring* for *ſtring of ſilk*, and *gold-ring* for *ring of gold*. The Greek and Latin do not abound with the ſame analogy, and therefore frequently uſe the perſonal pronoun in the genitive as equivalent to the pronominal adjectives.

The reciprocal or reflex pronoun *ſelf* is added to theſe pronominal adjectives: as *myſelf*, *thyſelf*, &c. The third perſon ſingular and plural by analogy ſhould be *his-ſelf* and *theirſelves*: but in order to humour the ear or the organs of ſpeech, theſe are changed into *himſelf* and *themſelves*. *Self* means an individual in oppoſition to another, and is derived from the Latin *ſolus*, alone, through the medium of the Anglo-Saxon *ſolus*, *ſoul*, Anglo-Saxon *ſaſel*, *ſelf*: hence alſo *ſoul*, which means that part of man in which conſiſts the vital principle in oppoſition to the body: *own*, often uſed to precede *ſelf*, is a corruption of the Anglo-Saxon *ogen*, which by the inſertion of the letter *g*, after the analogy of that language, is borrowed from the Latin *unus*. *Ownſelf*, therefore, is *oneſelf*.

Mr. Harris gives the following account of that ſpecies of adjectives called *definitives* or *articles*: "The viſible and individual ſubſtances of nature are infinitely more numerous than for each to admit a particular name. To ſupply this defect, when any individual occurs, which either wants a proper name, or whoſe proper name is not known, we aſcertain it as well as we can, by referring it to its ſpecies; or if the ſpecies be unknown, then at leaſt to ſome genus. For example, a certain object occurs with a head and limbs, and appearing to poſſeſs the power of ſelf-motion and ſenſation: if we know it not as an individual, we refer it to its proper ſpecies, and call it *dog*, or *horſe*, or *lion*, or the like. If none of theſe names fit, we go to the genus, and call it animal."

"But this is not enough: the thing at which we are looking is neither a ſpecies nor a genus. What is it then? An individual. Of what kind? Known or unknown? Seen now for the firſt time, or ſeen before, and now remembered? It is here we ſhall diſcover the uſe of the two articles *a* and *the*. *A* reſpects our primary perceptions, and defines individuals as unknown: *the* reſpects our ſecondary perception, and denotes individuals as known. To explain by an example: I ſee an object paſs by, which I never ſaw till now. What do I ſay? There goes *a* beggar with a long beard. The man departs, and returns a week after. What do I ſay then? There goes the beggar with *the* long beard. The article only is changed, the reſt remains unaltered. Yet mark the force of this apparently minute change. The individual, *once vague*, is now recognized as ſomething known, and that merely by the efficacy of this latter article, which tacitly inſinuates a kind of previous acquaintance, by referring the preſent perception to a like perception already paſt.

"The truth is, the articles *a* and *the* are both of them definitives, as they circumſcribe the latitude of genera and ſpecies, by reducing them for the moſt part to denote individuals. The difference between them, however, is this; the article *a* leaves the individual itſelf *unaſcertained*, whereas the article *the* aſcertains the individual alſo, and is for that reaſon the more accurate definitive of the two."

We give this ſtatement as that of an eminent grammarian, without ſubſcribing to it as juſt in all reſpects. It is not, we conceive, true, to ſay that the individual defined by *a* is always *unaſcertained*; nor does *the* neceſſarily imply a previous acquaintance, by referring the preſent perception to a like perception already paſt. And we cannot help obſerving that, if Mr. Harris and other writers on the ſubject had traced theſe words to their ſources, and thus aſcertained their primary meaning, their readers would have been more informed in one paragraph, than they otherwiſe could by the moſt elaborate treatiſe.

The article *a* is in truth the numeral adjective ἓν in Greek, *unus* in Latin, *een, an, ane*, in Anglo-Saxon: and the import of it preciſely correſponds with its original ſignification of *one*. *A* book is one book; *a* man is one man. Hence we may learn with certainty the following particulars. That it is enveloping the word in myſtery to call it an *article*, inſtead of calling it by the more appropriate name of *numeral adjective*, or *definitive*. That as it means *one* it cannot be prefixed to plural nouns, unleſs thoſe nouns be taken in a collective ſenſe. That the uſual rule, *a* becomes *an* before a vowel, ſhould be juſt reverſed in order to be true. "*An* becomes *a* before a conſonant." That the equivalent of the article *a* exiſts in Greek and in Latin, but is rejected as uſeleſs in thoſe languages; and that the frequent uſe of it in Engliſh and other modern language is ſo far from being neceſſary, that it is an incumbrance and inelegance. *I ſee man* would be as intelligible as when we ſay *I ſee a man*; and *they read book*, as definite, as *they read a book*; and this, from the nature of the caſe, juſt as in Latin, *video hominem, legunt librum*, where *unum* would be both unneceſſary and inelegant. The Engliſh *I ſee man*, and the Latin *video hominem*, are both equally indefinite in themſelves; but they are ſufficiently limited by the nature of our perception, and by previous experience. "The indefinite article," ſays the author of the treatiſe on Grammar in the Encyclop. Britannica, "is much leſs uſeful than the other; and therefore the Greek and Hebrew languages have it not, though they both have a definite article. In languages, of which the nouns, adjectives, and verbs have inflexion, no miſtake can ariſe from the want of the indefinite article; becauſe it can always be known by the terminations of the noun and the verb, and by the whole circumſtances predicated of the noun, whether a whole ſpecies or one individual be intended. But this is not the caſe in Engliſh. In that language the adjectives having no variation with reſpect to gender and number, and the tenſes of the verbs being for the moſt part the ſame in both numbers, it might be often doubtful, had we not the indefinite article, whether the ſpecific name was intended to expreſs the whole ſpecies or only one individual." All this reaſoning, however, appears to us fallacious, and only ſhews that even a wiſe and able man, ſuch as the writer of this article certainly is, will readily think that neceſſary and uſeful to which he has been accuſtomed, and therefore will ſeldom be at a loſs for ſome plauſible reaſons to juſtify it. In truth, the inflexions of adjectives and verbs in the learned languages alluded to, have no influence whatever in defining the extent of the general term, but ſerve merely to ſhew that they qualify that term, and depend upon it. The very example adduced by this writer ſhews the fallacy of his reaſoning: Εγενετο ανθρωπος απεϛαλμενος παρα θεου ὡ ονομα Ιωαννης. Here ανθρωπος as clearly denotes not the whole ſpecies, but an individual, as if it was written εἱς ανθρωπος, and that not becauſe of the ſingular correſpondence of εγενετο, nor from the termination of απεϛαλμενος. Of this there is an evident proof; εγενετο and απεϛαλμενος would be ſtill the ſame, though ανθρωπος had a ſpecific or collective ſenſe. But the individual ſenſe of the noun appears from the nature of the caſe, from the context, and eſpecially from the clauſe, *whoſe name was John*: and theſe circumſtances, which ſufficiently define it in Greek, would be ſufficient to define it in Engliſh, were it written "Man was ſent from God whoſe name was John" It is impoſſible to feel in this any ambiguity; and the expreſſion ſeems uncouth only becauſe we have been accuſtomed to the uſe of *a man* was ſent from God, &c.

Mr. Tooke derives *the* and *that* from the Anglo-Saxon verb *thean* or *thegan, to take*. But theſe definitives *exiſt in that language*, and why ſhould he attempt to derive them from any word, when they are already formed and employed in the ſame ſenſe? He ſeems to have been aware of this objection. And he adds, vol. ii. p. 60, "*The* (our article, as it is called) is the imperative of the ſame verb *thean*, which may very well ſupply the place of the correſpondent Anglo-Saxon article *ſe*, which is the imperative of *ſeon, videre*. For it anſwers the ſame purpoſe in diſcourſe to ſay—*ſee man*, or *take man*." The Engliſh *take*, and the Anglo-Saxon *thegan*, which this writer would lead us to regard as a primitive northern word, is only the Greek δεχω, *to accept*—*Take this*, therefore, means, *receive this*.

Light is the medium of ſight, and hence, in the moſt ancient languages, the word ſignifying light gave birth to verbs ſignifying *to ſee*. Thus the Hebrew צוא, *tsa*, pronounced in Arabic *thao*, but in Perſian *ſeea, light*, is the parent of the Anglo-Saxon *ſeon* and our *ſee*, which accords with the Perſian pronunciation, and alſo of the Anglo-Saxon article *ſe* or *ſeo*, or, as we found it, conformably to the Arabic, *the*. It is remarkable the article ὁ in Greek is founded entirely on the ſame principle, though derived from a very different word For its original appears to have been the Hebrew article ה, which probably was ſounded *hu* or *ho* ſhort, and which is but an abbreviation of הא, *ha*. Now the uſe of this laſt conſiſts in directing the attention to an object, and anſwers to *en* or *ecce* in Latin, and *behold* in our own tongue. And as the neceſſary conſequence of looking upon *a thing* is to ſee it, as diſtinguiſhed from other things, hence ה in Hebrew, ὁ in Greek, *the* in Engliſh, from ſignifying to *perceive*, through the medium of light, came to ſignify an effect of perception, namely, the diſtinction or oppoſition which the thing ſo ſeen has to other things which may be related to it.

From this account we may gather the following particulars reſpecting the nature and uſe of the definitive article. Its primary force conſiſts merely in directing the *eye* or the *attention* to an object; and the definitive power aſſigned to it is rather an effect of the ſight where the object is preſent, or of the mind in drawing the neceſſary inference, where the object is previouſly deſcribed or ſpecified. If this account be juſt, the aſſertion of Mr. Tooke, that the article, in combination with a general term, is a mere ſubſtitute for a particular term, (ſee vol. i. p. 69.) is erroneous. The article is only an *index*; having indicated the thing intended it does no more: the eye or the mind does the reſt, and the general term is defined or made particular, by being brought under immediate inſpection. It is neceſſary to ſubjoin the general term to the article, becauſe it is neceſſary to ſpecify the object intended; but the reſtriction of the ſpecific or general noun to that individual object is a *conſequence* of the article, rather than a power belonging to it. The article therefore cannot be a mere ſubſtitute, to do that which is done by another principle, namely, the eye or the mind.

The article ſerves as an index to ſpecify an object hitherto *unknown*, as well as one previouſly known; and thus Mr. Harris's diſtinction, that *a* reſpects our primary perception, and denotes individuals as unknown; *the* reſpects our ſecondary perception, and denotes individuals as *known*, is unfounded. The index indeed may be directed to a paſt event or object, thus to make it the ſubject of inſpection a ſecond time. In this view Mr. Harris's poſition is true, but the uſe of the article is far more general, and by no means confined to ſuch caſes.

The article *the* is the ſame in origin, and often in uſe the ſame with *that*, and indeed in the Anglo-Saxon *that* is only the neuter gender of *the*; and Mr. Tooke ought to have made this remark inſtead of repreſenting each as independent of the other.

This definitive is in our tongue variouſly applied; and the objects of its application are ſo diſtinct and different, that it has been thought to change its nature, and to belong to different parts of ſpeech. And Mr. Tooke has the merit of being the firſt to ſhew that in all circumſtances, *that* retains one and the ſame character. Let us briefly conſider its various applications. And *firſt*, it is uſed to bring under the eye of the [illegible], *i. e.* to define individual objects; as *that* book. In this ſenſe it is oppoſed to *this*, anſwering to *ille* as oppoſed to *hic* in Latin. Ille, *that*, denotes the remoter of two objects; hic, *this*, the nearer. "Alexander and Julius Cæſar were great commanders, *that* (ille) conquered Aſia; *this* (hic) ſubdued the Gauls—*that,* meaning Alexander as the fartheſt off; *this*, Julius Cæſar, as the neareſt." In ſuch a ſentence it would be more uſual to ſay the *former* and the *latter*. *Secondly*, *that* is frequently uſed to characterize *a whole clauſe*, which is the object of a tranſitive verb, thus ſerving to fix the attention on what is going to be ſaid, and by that means to render it emphatic and prominent. Thus, "I wiſh you to believe *that* (that thing which I am going to ſay, namely,) I will not hurt a fly;" which Mr. Tooke thus reſolves, "I would not willingly hurt a fly; I wiſh you to believe *that* aſſertion." In this application it anſwers to *quod* in Latin. *Thirdly*, *that* is an index to point out the *end* or *purpoſe* which a perſon has in view, and as ſuch precedes a verb in the ſubjunctive mood, expreſſing that end thus: "Thieves riſe in the night *that* they may ſteal."—"Thieves riſe in the night, *that* being their purpoſe, namely, they might ſteal." In this ſenſe it correſponds to the Latin conjunction *ut*, which, perhaps, led to the error of conſidering *that* as a conjunction in the ſecond and third ſenſes. *Fourthly*, it is an index pointing to a noun in the preceding clauſe, and is a ſubſtitute for that noun, or rather it agrees with that noun implied, though never expreſſed. "The man, *that* hath not muſic in himſelf, is fit for treaſon." Here the firſt clauſe, *the man*, is repreſented as definite, while the reader as yet is not able to recogniſe it as ſuch. What man is fit for treaſon? To preclude the neceſſity of this queſtion, a clauſe is introduced, *that* man, namely, he who hath not muſic in himſelf. In this ſentence *that* is thought to be a relative equivalent to *who*, which may be ſubſtituted for it. But in reality it is ſtill a definitive, uſed to aſcertain the preceding ſpecified noun, which has the form of being definite without being really ſo; and the preceding noun is to be repeated, or, as *that* is *deſcriptive,* a generic or ſpecific noun of the ſame import is underſtood to be introduced. Thus the man, namely, *that ſort of man*, who hath not muſic in himſelf, is fit for treaſon. The ſubject of diſcourſe may be *plural*, and yet the ſingular form of *that* may, on this ſuppoſition, be uſed. "The men *that* have not muſic in themſelves, are fit for treaſon," *i. e.* the men, *that ſort of men*, namely, who have not muſic in themſelves, are fit for treaſon: and this is the ſolution of the apparent anomaly of *that* being uſed in both numbers, without variation, when taken relatively.

We come next to ſpeak of the *relative pronoun*, which Mr. Harris thus explains, p. 77. "But beſides thoſe there is another pronoun (in Greek ὃς, ὅσις, in Latin *qui*, in Engliſh *who, which, that*), a pronoun having a character peculiar to itſelf, the nature of which may be explained as follows. Suppoſe I was to ſay *light* is a body,—*light* moves with great celerity. Theſe would apparently be two diſtinct ſentences. Suppoſe, inſtead of the ſecond *light*, I were to place the prepoſitive pronoun *it*: *Light* is a body; *it* moves with great celerity; the ſentence would be ſtill diſtinct and two. But if I add a connective (as for example an *and*) ſaying light is a body, and it moves with great celerity; I then by connection make the two into one, as, by cementing many ſtones I make one wall.

"Now it is in the united powers of a connective and another pronoun, that we may ſee the force and character of the pronoun here treated. Thus, therefore, if in the place of *and it* we ſubſtitute *that* or *which*, ſaying *light* is a body, *which* moves with great celerity; the ſentence ſtill retains its unity and perfection, and becomes, if poſſible, more compact than before. We may with juſt reaſon, therefore, call this pronoun the *ſubjunctive*, becauſe it cannot, like the prepoſitive, introduce an original ſentence; but only ſerves to ſubjoin one to ſome other which is previous."

This account, though elegant and ſpecious, we nevertheleſs deem erroneous; becauſe the relative pronouns in all languages are the ſame in their origin and uſe with the articles or definitive pronouns. In Greek ὃς is only the article ὁ with ς annexed after the analogy of that termination in Greek nouns. Hence the reaſon why ὁ and ὃς are, by the more ancient writers, ſuch as Homer and Herodotus, uſed for one another, either as demonſtrative or relative pronouns. The Latin *hic* is alſo the article ὁ with a guttural annexed—*hoc;* while *qui*, which Scaliger, and after him Mr. Tooke, derive from καὶ ὁ, is no other than the Perſian *ke* or *che*, *who, which.* Moreover, *quis* is the Oriental *kis*, *who* or *what*; and it is remarkable that in Hindooſtan *kis* is redoubled *kis kis*, and this has been imported into Latin *quiſquis*. Finally, our *who* is the Greek ὁ, having the labial *w* ſubſtituted for the aſpirate, which is a broad and general analogy, by which words in Latin and the Anglo-Saxon are formed from Greek or from the Oriental tongues. *Which* is the neuter termination of ὁ, formed on the ſame principle as *hoc* in Latin, that is, a guttural is annexed to *who, whoc, which.* And this is the reaſon that, while *who* is applied to perſons, *which* is made to ſtand for inanimate things.

As the relative and definitive pronouns have the ſame origin, they are alſo the ſame in uſe. For in Latin the relative always ſuppoſes the antecedent to be repeated, and is repeated when obſcure or doubtful. In our own tongue, indeed, *who* never coaleſces with the antecedent noun, and is therefore a *ſubſtitute* for it, and this peculiarity in our own tongue has cauſed *who*, with its other caſes *whoſe*, *whom*, to drop its nature as a definitive, and to become really a *pronoun*, *i. e.* a ſubſtitute for a noun. This peculiarity has alſo obtained in regard to *he*, which was the Hebrew and Greek article ה, *ha*, or ὁ. And this is the reaſon why the article in Homer may be often rendered by *he* in our own tongue. Dr. Middleton, not perceiving this circumſtance, was led, in a voluminous work publiſhed on the Greek article, to ſuppoſe that the Greek article is in its nature a *perſonal pronoun*, and may be always reſolved into a pronoun. The foundation being thus fallacious, the whole ſuper-ſtructure, however learned and elaborate, is frivolous and uſeleſs.

We obſerve farther that *hic*, *ille*, and *is*, which are really definitives, often refer, like *qui*, to a preceding noun, and for this reaſon have a claim equally juſt to be called relative pronouns. Thus, "Deus nobis hæc otia fecit; namque erit *ille* mihi ſemper Deus; *illius* aram ſæpe tener noſtris ab ovilibus imbuet agnus." Here the firſt *ille* is *ille homo*, or *ille juvenis*, meaning *Auguſtus*, elegantly kept out of ſight, the reader being left to conceive of him only as a *god;* while *illius* is illius dei, *of that god.* "Tres littore cervos proſpicit errantes, *hos* tota armenta ſequantur, *i. e.* hos cervos." "Cognoſcimus Deus ex operibus ejus," we know God from the works of the ſame—*ejus dei.*

Becauſe the relative *qui* is thus a definitive, the defined noun, when not antecedent, is made to ſucceed it in Latin and in Greek, as " Maximis laboribus conſequuntur eam, quam ex diſcendo capiunt, voluptatem;"—literally, with the greateſt toil they purſue that, which pleaſure, (for that pleaſure, which) they derive from ſtudy. " Quas condidit arces, ipſa colat,"—let her inhabit which citadels ſhe built, *for*, let her inhabit the citadels which ſhe built. In our own tongue ſuch an arrangement is not allowed, or even intelligible, becauſe here the relative is really a ſubſtitute for the noun preceding it, and refuſes to coaleſce with it as an adjective. And it is obvious to remark in this place, that with the exception of *who* in Engliſh, the articles or definitives are not *pronouns*, but *adjectives*, numeral or reſtrictive, agreeing with a noun expreſſed or underſtood, and to be ſupplied from the context or the preceding clauſe. We remark, finally, that as articles are definitives, the Latin tongue has not only *one* but ſeveral articles, which it is erroneouſly ſuppoſed to want. Thus, hic homo, *this man*, ille homo, *that man*, is homo, *the ſame man*, ipſe homo, *that very man*, are phraſes, either of which is equally definite and emphatic with our *the man*, and on many occaſions preciſely the ſame with it.

Before we quit this ſubject we ſhall advert to a queſtion propoſed and ſolved by Mr. Tooke, vol. i. p. 273. " What is AS?—The truth is that *as* is alſo an article; and however, and whenever, uſed in Engliſh, means the ſame thing as *it*, or *that*, or *which*. In the German, where it ſtill evidently retains its original ſignification and uſe, (as *ſo* alſo does,) it is written *es*." Now, if Mr. Tooke had properly underſtood the nature of the article, he would not have made this aſſertion. *As* indeed, like the article, is an *index*, but it is an index directing the mind from one object to another, and the conſequence of its being ſo directed is the perception of ſome *reſemblance* between them. Accordingly *as* is ὡς, an adverb of ſimilitude in Greek, which being inverted (as is often the caſe with monoſyllabic words), has become *ſo*. On the other hand, the conſequence of the indication conveyed by the article is not to the obſervance of ſome likeneſs between the objects ſpecified, but the limitation of the general term to the individual object, circumſcribed by the eye or the mind by being ſo indicated.

In a note this writer adds: " Dr. Lowth, amongſt *ſome* falſe Engliſh which he has recommended, and *much* good Engliſh which he has reprobated, ſays, *ſo-as*, was uſed by the writers of the laſt century to expreſs a conſequence inſtead of *ſo-that*. Swift, I believe, is the laſt of our good writers who has frequently uſed this manner of expreſſion." If *that* denote *end* or conſequence, the third ſenſe we have *aſſigned* to it in the preceding page, and if *as*, on the other hand, ſignify *ſimilitude* between two objects, *ſo as* is, as Dr. Lowth ſtates, very improper; while *ſo that* alone is good Engliſh and good ſenſe: and Mr. Tooke is himſelf guilty of the charge he brings againſt Lowth, namely, of recommending ſome falſe, and reprobating much good Engliſh. We cannot help obſerving that the object of compariſon marked by *as* is often implied, and is to be gathered from the context; as in the following ſtanza:

Save that from yonder ivy-mantled tower,
  The moping owl does to the moon complain
Of *ſuch as*, wandering near her ſecret bower,
  Moleſt her ancient ſolitary reign.

i. e. complain of ſuch *perſons*, as *thoſe who* wandering, &c.

The Origin and Properties of Verbs.

We ſhall begin this part of our ſubject alſo with an extract from Mr. Harris, becauſe his opinion, though plauſible, is erroneous, and has been the means of leading other grammarians, who followed his authority, into error. " We are now," ſays he, " to deſcend to the common herd of attributes, ſuch as *black* and *white, to write, to ſpeak, to walk*, &c. among which, when compared and oppoſed to each other, one of the moſt eminent diſtinctions appears to be this. Some, by being joined to a proper ſubſtantive, make, without farther help, a perfect aſſertive ſentence; while the reſt, though otherwiſe perfect, are in this reſpect deficient. To explain by an example, when we ſay *Cicero eloquent*, *Cicero wiſe*, theſe are imperfect ſentences, though they denote a ſubſtance and an attribute. The reaſon is, that they want an aſſertion to ſhew that ſuch attribute appertains to ſuch ſubſtance. We muſt therefore call in the help of an aſſertion elſewhere, an *is* or *was*, to complete the ſentence, Cicero *is* wiſe, Cicero *was* eloquent. On the contrary, when we ſay *Cicero writeth*, *Cicero walketh*, in inſtances like theſe there is no ſuch occaſion, becauſe the words *writeth* and *ſpeaketh* imply, in their own form, not an attribute only, but *aſſertion* likewiſe. Hence it is they may be reſolved the one into *is* and *writing*, the other *is* and *walking*.

" Now all theſe attributives, which have this complex power of denoting both an attribute and an aſſertion, make that ſpecies of words which grammarians call *verbs*. If we reſolve this complex power into its diſtinct parts, and take the attribute alone, without the aſſertion, then have we *participles*. All other attributives, beſides the two ſpecies before, are included together in the general name of adjectives; and thus it is that all attributives are either verbs, participles, or adjectives. Beſides the diſtinctions abovementioned, there are others which deſerve notice. Some attributes have their eſſence in motion; ſuch are *to walk, to fly, to ſtrike, to live*. Others have it in the privation of motion; ſuch are *to ſtop, to reſt to ceaſe, to die*. And laſtly, others have it in ſubjects which have nothing to do with either motion or its privation; ſuch are the attributes of *great* and *little*, *white* and *black*, *wiſe* and *fooliſh*, and in a word the ſeveral *quantities* and *qualities* of all things. Now theſe laſt are *adjectives;* thoſe which denote *motions* or their privation are either *verbs* or *participles*."

" Of all the conſtituent parts of ſpeech," ſays the writer in the Encyclop. Britannica, 58, " none has given the grammarians greater trouble than the verb. The vaſt variety of circumſtances which it blends together in one word, throws very conſiderable difficulties in the way of him who attempts to analyſe it and aſcertain its nature; at the ſame time that by its eminent uſe in language, it is entitled to all the attention which can be beſtowed upon it. It ſhould ſeem that the firſt object of our inveſtigation ought to be the *characteriſtic* of the verb, or that which all theſe words have in common, and which conſtitutes them verbs, diſtinguiſhing them from every other ſpecies of words. Now it is obvious to the ſlighteſt attention, that every verb, whether active, paſſive, or neuter, may be reſolved into the ſubſtantive verb *is*, and another *attributive:* for *loveth* is of the ſame import as *is loving;* and *amat* with *amans eſt*.

" But *loving* and *amans* are not verbs; whence it follows that the characteriſtic of the verb, that which conſtitutes it what it is, and cannot be expreſſed by other words, muſt be that which is ſignified by the word *is;* and to us that appears to be neither more nor leſs than *aſſertion*.

" Aſſertion therefore, or predication, is certainly the very eſſence of the verb, as being that part of its office, and that part only, which cannot be diſcharged by other kinds of words. Every other circumſtance which the verb includes, ſuch as *attribute, mode, time*, &c. it may be poſſible to expreſs by adjectives, participles, and adverbs; but without a verb it is impoſſible to *predicate*, to *affirm*, or *deny*, any one thing of any other thing. The office of the verb, when ſtripped of all accidental circumſtances, ſeems to be merely this: to join together the ſubject and predicate of a propoſition; its powers are analogous to thoſe of the ſign + in algebra, which does not affect the ſeparate value of the quantities between which it is placed, but only indicates their *union* or *coaleſcence*." The writer then, in illuſtration of this theory, takes the examples uſed by Mr. Harris, and then adds, "in reſolving every verb, whether active, paſſive, or neuter, into the ſubſtantive verb *is*, and another attributive, we have the honour to agree with all the grammarians."

We reſpect the opinion of other grammarians, and that of this writer in particular, but we cannot think it an honour to agree with him and his predeceſſors on this ſubject; but we rather think it an honour to differ with them, becauſe we conceive them to be in an error. Now the moſt ſure way to aſcertain the characteriſtic of a verb, or that which conſtitutes its eſſence, is to attend to that operation of the human mind by which verbs have been formed. But as the affirmative *is* is thought eſſential to all others, we ſhall begin with this. And Mr. Harris thus explains it, p. 88, "Previous to every poſſible attribute, whatever a thing may be, whether black or white, ſquare or round, wiſe or eloquent, writing or thinking, it muſt *firſt* of neceſſity *exiſt*, before it can poſſibly be any thing elſe. For exiſtence may be conſidered as an *univerſal genus*, to which all things, of all kinds, are at all times to be referred. The verbs, therefore, which denote it, claim precedence of all others, as being eſſential to the very being of every propoſition, in which they may ſtill be found either expreſſed or by implication; expreſſed, as when we ſay "the ſun is bright;" by implication, as when we ſay "the ſun riſes;" which means, when reſolved, "the ſun is riſing."

According to this explanation *exiſtence* is the primary idea of *is*; and Mr. Harris is little conſiſtent with himſelf when, in reſolving active verbs into this and another attributive, he ſuppoſes it to mean *aſſertion*. But let us deduce a more adequate idea of it from examples—*God is good; His food was locuſts and wild honey; If we be virtuous we ſhall be happy*. In the firſt of theſe examples *is* connects *good* with *God*; ſo in the ſecond *was* connects *locuſts and wild honey* with *food*, and aſſerts, that with regard to John they were the ſame. In the third inſtance, happy is, by *ſhall be*, repreſented a quality of *we*. For this reaſon the following terms would be more appropriate than any other. The leading noun the *ſubject*, the thing connected the *predicate*, and the verb connecting them the *connecting verb*. Thus, *God* is the ſubject, *is* the connecting verb, and *good* the predicate; and ſo in all other inſtances.

If then *is* be the characteriſtic or eſſential idea of every verb, and if farther, as appears from fact, the primary idea of *is* denotes *connection*, it follows that not *aſſertion*, as the grammarians have hitherto ſuppoſed, but *connection*, is that which conſtitutes verbs, or that which diſtinguiſhes them from other ſpecies of words. But the connecting verb itſelf will not appear *neceſſary*, if we judge of its uſe in the ancient languages, the *juxtapoſition* of the ſubject and predicate being ſufficient to ſupply its place. Thus μακαριοι ὁι ελεημονες, *bleſſed the merciful*. Here μακαριοι, being placed by the ſide of ὁι ελεημονες, ſuggeſts that it belongs to it, and by virtue of this ſuggeſtion conveys to the mind as full and complete a propoſition as though the connecting verb had been inſerted. Thus too in Latin, *Homo præcipuum opus Dei*, man the principal work of God, meaning man *is* the principal work of God. Thus alſo in Hebrew, "And Moſes ſaid unto the Lord, I not eloquent, *i. e.* I *am* not eloquent, Exod. iv. 10. And Moſes ſaid unto God, who I, that I ſhould go unto Pharaoh; and God ſaid, certainly I will be with thee, and this token unto thee, *i. e.* this *ſhall be* a token unto thee," iii. 11, 12. In this tongue, indeed, the ſubſtantive verb is comparatively of rare occurrence, and its place is ſupplied by the collocation of the terms to be connected, a principle in itſelf extremely ſimple, and ſuggeſted by the great law of the human mind. In Greek and in Latin its uſe indeed is more frequent; and it is remarkable that where it does occur, it generally occurs either in the beginning or the end of the clauſe, and not in the middle, a circumſtance which aroſe from a deſire of keeping together words that are related as ſubject and predicate. Now Mr. Harris and other grammarians, overlooking the force of juxtapoſition, and judging of the importance of the ſubſtantive verb from its frequent uſe in modern ſpeech, have hence ſuppoſed that it is abſolutely neceſſary to the exiſtence of language, and that no propoſition can be communicated without it. And what is more remarkable ſtill, "they have repreſented a word as eſſential to a verb, which, ſo far from being neceſſary to a verb, is not neceſſary even to language."

Verbs expreſs the operations or the active qualities of things; and as the growth of words correſponds to the growth of our ideas, it follows that verbs originally were the names of things; but by combining them with the perſonal pronouns, they became, in conſequence of the aſſociation of ideas, to expreſs not *things*, but their *operations*.

The converſion of nouns into verbs we will illuſtrate by an example in the Greek tongue. Mr. Jones, in his Grammar of that language, has ſhewn that the perſonal terminations of the Greek verbs are but corruptions of the perſonal pronouns, and all the variations of mood, tenſe, number, and perſons have originated in theſe ſix elementary principles, thus:

εγω ω, *I*, ἡμεις ομεν, *we*,
συ εις, *thou*, ὑμεις ετε, *ye*,
ὁυ ει, *he*, ὁυτοι ουσι, *they*.

Now let theſe in their corrupted ſtate be annexed to any noun, for inſtance to οινο-ς, *wine*; and we ſhall have οινο-ω, *wine I*; οινο-εις, *wine thou*; οινο-ει, *wine he*; οινο-ομεν, *wine we*; οινο-ετε, *wine ye*; οινο-ουσι, *wine they*. When the attention of the ſpeaker or hearer was fixed on the firſt of theſe combinations, the union of the two words which ſignified *himſelf* and *wine* could not fail of bringing to his mind the circumſtances which he had *previouſly experienced* or *obſerved* in regard to that liquid; and hence he neceſſarily recalled the idea of *making* or *taſting wine*, or *drinking wine*. Conſequently, the two terms thus combined he naturally employed to expreſs one of thoſe notions. A ſimilar proceſs took place with regard to the remaining five combinations. And thus have we in Greek, and other languages, verbs diverſified by *ſix perſons*. This extenſion of the names of things to ſignify the actions which thoſe things have been obſerved to perform, is, it is obvious, founded on the law of aſſociation, and may be illuſtrated by many inſtances in all languages. But the principle is not ſo clear in any tongue as it is in Hebrew, where the perſonal pronouns annexed to the verb are preſerved with little variation from what they are in their independent ſtate.

In the above, and ſimilar other examples, the agent, and that which is the effect or object of the action, combine to expreſs that action; but in other inſtances, the name of the agent alone is ſufficient to expreſs its operation. Thus, "the ladies *fan* themſelves;" "the plumy people *eye* the falling verdure." Now having previouſly obſerved the uſe or action of the *fan*, and learnt in ourſelves the *effect* of the eye, being alſo previouſly aware that in a ſimple direct propoſition, the ſecond uſually denotes operation, we ſhould immediately infer that *fan* and *eye* here expreſs not the things meant by them but their active qualities; in other words, our previous aſſociations would inſtantly convert thoſe nouns into verbs, though we had never ſeen them ſo uſed before.

From this account of the deduction of verbs from *nouns* and *pronouns*, we may aſcertain their nature and properties. A verb is a word borrowed from a thing to expreſs the action of that thing. It implies *connection*, the connection of an agent and its object, or more generally the connection of cauſe and its effect. But this connection is not expreſſed by an independent word but by the juxtapoſition, or the combination into one word of the agent and its object. On the other hand, it does not imply *affirmation* or *aſſertion*, as grammarians have hitherto ſuppoſed, becauſe no word expreſſive of this enters into its compoſition. The operation of a verb is indeed poſitive; and therefore that implication which writers on this ſubject call *aſſertion* may be conſidered to belong to it, but this is rather an inference formed by the mind than a property inherent in the verb; and is confined to a certain mood or form of it. We underſtand the *indicative* to aſſert, but this aſſertion is loſt in the *imperative*, *ſubjunctive*, and *infinitive*. So that if *aſſertion* be eſſential to a verb, a verb ceaſes to be a verb in theſe moods.

A verb implying an abſtract idea, and therefore often indefinite and obſcure, may be aſcertained in regard to its meaning by recurring to the noun from whence it has been derived. This noun, which probably is the name of ſome ſenſible object, ſuggeſts its *primary ſenſe*, a circumſtance of great importance in the conſtruction of a *philoſophical dictionary*, a work exiſting in no language, and much wanted in every language. "The moſt neceſſary verbs," ſays Dr. Crombie in his Engliſh grammar, p. 81. in every language, are thoſe, the ſignification of which is the moſt extenſive, and which would originally be of moſt general uſe, ſuch as verbs denoting exiſtence, poſſeſſion, acting and being acted upon. Of this kind in our language, are the verbs *to be, to do, to have.*"

We will take theſe, which this grammarian has cited, as examples to illuſtrate our theory. In the Great Indian language, *baa-o* is *air*, and *air* is the medium of exiſtence; it gave birth to the verbs of *being* in moſt languages. Hence *bodan* in Perſian; *be* in Anglo-Saxon and Engliſh; βιοώ in Greek, and the digammated *vivo* in Latin, and *bwy* in Celtic. On the ſame principle the Hebrew אור, *awr, light, air*, is the parent of our words *are, were, was*, and of the Latin *ero, eram*. *To do* is to put forth power: and this, with other verbs of the ſame kind, are borrowed from ſuch objects as put forth their fruits, ſuch as herbs, trees, the earth. Thus, ποιη, *the graſs*, gave birth to ποιεω, *to produce*. Hence ſuch phraſes as ποιειν καρπον, *to produce fruit*; δρυς, *is the oak*; and hence δραω, *to bring forth as the oak*; φαγος, *the beech*, hence *facio*, to yield fruit as the beech; פרח, *pharag*, means *a flower*; hence πραγω or πρασσω, *to effloreſce* or *fructify*. In Chaldee ארק, *aruk*, is *the earth*; hence in Greek εργον, εργαζω, and our verb *work*. In the ſame way δοω, *do, to give, yield*, is the real ſource of the Engliſh *to do*.

Now, it is very evident that the principle which converted one of theſe nouns into a verb, is that which converts all other nouns into verbs. If this be the caſe, Dr. Crombie and other followers of Mr. Horne Tooke are miſtaken, when they ſuppoſed that the junction of one of theſe verbs to a noun, cauſed that noun in proceſs of time to aſſume the character of a verb. And here we may obſerve that an infinitive verb, as ſeparated from its agent or ſubject, is in reality an *abſtract noun*. In this ſtate the prepoſition *to* is prefixed to it, and its uſe is to be aſcertained from its etymology. In Arabic אתא is a verb which ſignifies motion to a place or object. Hence in Celtic (*atto*, it) became a prepoſition denoting an *end*, or the point to which motion tended. In paſſing to Perſia it dropped the initial vowel, and in the form of *taa* it denotes, in Perſian, the interval in which motion reaches its object, or that object itſelf, and thus became the parent of our *to*, which it perfectly reſembles in ſound and ſenſe. *To* then denotes that point of time or place to which motion or action tends, and in which it terminates; and prefixed to an infinitive verb, thus converted by abſtraction into a ſpecies of verbal nouns, holds it forth as the object to which the preceding verb is directed; thus, *I deſire to learn*, I deſire, and the object or end of that deſire is *learn* or *learning*. He commanded me to tell you, he commanded, and the object which that command reſpects, is, that I ſhould tell you. This explanation appears juſt, from the circumſtance that when the infinitive verb is the immediate ſubject of action rather than a more remote object to which an action tends, the prepoſition *to* is dropped; as *I do plow, i. e.* I uſe the plough, or act the plough.

Let us next ſee what Mr. Tooke ſays on this ſubject. "The prepoſition *to*," ſays he, vol. i. p. 350, "is the Gothic ſubſtantive *taui*, or *tauhts, i. e. act, effect, reſult, conſummation*. Which Gothic ſubſtantive is, indeed, itſelf no other than the firſt participle *tauid*, or *tauids*, of the verb *taugan, agere*. And what is done is *terminated, ended, finiſhed*. After this derivation, it will not appear in the leaſt myſterious or wonderful that we ſhould, in a peculiar manner in Engliſh, prefix this ſame word *to* to the infinitive of our verbs. For the verbs in Engliſh not being diſtinguiſhed, as in other languages, by a peculiar termination, and it being ſometimes impoſſible to diſtinguiſh them by their place, when the old termination of the Anglo-Saxon verbs was dropped, this word *to, i. e. act*, became neceſſary to be prefixed, in order to diſtinguiſh them from nouns, and to inveſt them with the verbal character. For there is no difference between the noun *love*, and the verb *to love*, but what muſt be comprized in the prefix *to*." And he goes on, p. 355, "*Do*, the auxiliary verb, as it has been called, is derived from the ſame root, and is, indeed, the ſame word as *to*. The difference between a *t* and a *d* is ſo very ſmall, that an etymologiſt knows by the practice of languages, and an anatomiſt by reaſon of that practice, that, in the derivation of words, it is ſcarce worth regarding. And, for the ſame reaſon that *to* is put before the infinitive, *do* uſed formerly to be put before ſuch other parts of the verb which likewiſe were not diſtinguiſhed from the noun by termination. As we ſtill ſay—I do love, inſtead of I love. And I *doed*, or *did* love, inſtead of I loved. But it is worth our while to obſerve, that if a diſtinguiſhing termination is uſed, then the diſtinguiſhing *do* or *did* muſt be omitted, the *termination* fulfilling its office. And, therefore, we never find—*I did loved*, or he *doth loveth*. But I did love, *he doth love*."

It is neceſſary briefly to expoſe what we conceive to be the fallacy and abſurdity of this reaſoning. *To*, in ſound and ſenſe, is the fartheſt poſſible from the Gothic *taugan*, which is only the Greek τευχω, *to fabricate*, the true origin of *to* being the Perſian *taa*, which has preciſely the ſame meaning with it. It is altogether unneceſſary to prefix the *to*, in order to diſtinguiſh the verb from its correſponding noun, becauſe this is done by the context, or the collocation of the verb; and what is moſt remarkable, when *to* is prefixed, the verb loſes its verbal character, and becomes a noun by abſtraction. That an infinitive verb has the nature of an abſtract noun, is manifeſt from this. In all languages it may be made the ſubject or object of diſcourſe; and, in Greek, it admits of the article before it, as nouns do; and in all inſtances whatever, an abſtract noun, where ſuch exiſts, may be ſubſtituted for it.—I deſire to learn, *i. e.* I deſire learning.—To excel in learning is honourable, *i. e.* excellence in learning is honourable. So then, according to Mr. Tooke, *to* is put before a verb to diſtinguiſh it as a verb when it has ceaſed to be a verb—when, from a verb, it is become a noun. And the reaſon why we ſay *he doth love*, inſtead of *he doth loveth*, is not that the termination ſupplies the place of *to*, but becauſe *loveth* and *love* are one a verb, the other a noun, which laſt does not admit ſuch a termination.

The converſion of *to* into *do*, ſo as to become a verbal index, is a conceit of this writer, equally unwarrantable. *Do*, as we have ſhewn, is the *identical* Latin *do, to give, to place, to produce*, or *put forth*, where it has ſuch meaning, in the following phraſe—*dare operam*, to put forth exertion, *i. e.* to exert, endeavour. And yet Mr. Tooke has been followed and ſupported by all ſubſequent grammarians in the above incorrect and inconcluſive reaſoning. "The form," ſays Dr. Crombie, p. 83, "of the infinitive *to love*, is, doubtleſs, the ſame as *do love*, thus denoting the ſimple energy of the emotion, ſignified by the noun, *d* and *t* being kindred letters, and eaſily convertible. To love, therefore, means *act love, do love*, the word *do* or *to* inveſting the noun with a ſort of verbal character. The infinitive, then, expreſſes ſimply the action or energy of that attribute which is denoted by the verb, uncompounded with the various accidents of mood, tenſe, number, and perſon." This laſt ſentence is a juſt deſcription of the infinitive mood which Dr. Lowth very properly calls the *ſubſtantive mood;* and it is a correct deſcription of an abſtract verbal noun. How then can *to* or *do* inveſt the noun with a ſort of verbal character; when, if it be an index of any thing, it is an index of a verb changed into a noun? A reſpectable writer on grammar, in the New Britiſh Encyclopædia, p. 31, following the tract which Horne Tooke has pointed out, thus adds: "The infinitive mood, as it is commonly called, is the verb diveſted of its peculiar force, *viz.* of affirmation, and uncompounded with thoſe words which render it expreſſive of perſon, number, &c. and in the modern languages of time: but it ſeems erroneous to conſider this as the fundamental form of the verb, where it has any diſtinguiſhing termination; it is then the *noun ſtate* of the word, with a termination added to it, to ſhew that it is to be employed as a verb. Thus, in the Anglo-Saxon *thean, the* is the fundamental form of the verb, and *an* is the *verbalizing adjunct*. Now, as the imperative form of the verb is nothing more or leſs than the ſimple verbal name, unattended with the inference of affirmation, this may be conſidered the fundamental form: and in the Latin in particular the variations of flexion are traced with the greateſt advantage from this ſource."

It is curious to obſerve the contradictions and abſurdities into which writers plunge themſelves, when they have adopted erroneous poſitions to account for the phenomena of language. Mr. Tooke, aſſenting to the ancient Stoics, thinks the pureſt ſtate of the verb to be the infinitive, and yet agrees with his followers in making *affirmation* or *aſſertion* to be the eſſence of a verb. But it is allowed that a verb drops its affirmation in the infinitive; ſo that, according to this reaſoning, a verb is in its pureſt ſtate when without its eſſence. Again, the infinitive is here not improperly called the *noun ſtate, i. e.* an abſtract noun, with the prefix *to* in our tongue; but in the Anglo-Saxon with the affix *an*, to ſhew that it is a verb: and as this is a new idea, *an*, in a new language, is called the *verbalizing adjunct*. But what evidence is there for ſaying that *an* performs this office? No evidence at all, but a falſe aſſumption. We have already ſaid that the Gothic and Anglo-Saxon *an* is but the Greek infinitive ειν, or (in verbs in αω), αν, which is the ſame without the change of a letter. We have this further evidence of the derivation of the Northern language from the Greek, in this reſpect, that in this latter the imperative, inſtead of being the fundamental form of the verb, is, by corruption, derived from the infinitive. Thus, γραφειν was the old infinitive; γραφειν was alſo the imperative; but the final ν being, by degrees, dropped, it became γραφε. And it is remarkable, that in the Anglo-Saxon the imperative is derived from the infinitive, in the ſame manner preciſely as the imperative is from the infinitive in Greek; and this correſpondence, added to the identity of the termination, we deem a ſufficient proof that the Northern, in this reſpect, is no other than the Greek tongue. The Latin imperative is borrowed from the Greek, as is evident on inſpection;—γραφε, γραφετω; *ſcribe, ſcribeto.* And the poſition, that the variations of inflexion may be traced with advantage from the Latin imperative, is a fancy, which is contradicted by that broad analogy by which the Latin verbs are formed from the preſent tenſe. It is worthy of remark, that the old Greek accords with the Hebrew, where the imperative is the ſame with the infinitive, and ſucceeds it in the paradigm of verbs. We ſhall only, on this ſubject, expreſs our ſurpriſe that, if theſe ſenſible men were deceived by adopting the notions of Mr. Tooke, they were not repelled by what appear to us to be contradictions. This grammarian gravely tells us that deliberate art had no concern in the formation of language: yet, in examining its phenomena, he recurs to minute mechaniſm and petty artifices, which, as being unwilling to allow the agency of a rational law in the human mind, he calls the *contrivances of language*.

We now proceed to conſider briefly the uſual diviſions of verbs into *active, paſſive*, and *neuter:* and this diviſion of verbs we pronounce to be extremely unphiloſophical. And firſt, as the expreſſion of active qualities is eſſential to verbs, there is no ſuch thing as a *neuter* verb. There are, indeed, verbs which denote *reſt*, or the ceſſation of *motion;* but we cannot uſe even theſe without connecting with them poſitive ideas: and as action is neceſſary to deſtroy or ſupport action, we can reſolve all apparent neuter into active verbs. Thus *to ſtand*, is *to cauſe to ſtop; to ſleep*, is *to enjoy repoſe; to ſit*, is *to hold one's ſeat.* Secondly, the diviſion of verbs into active and paſſive, though convenient in ſome languages, is incorrect and even abſurd in our own tongue. For all active verbs imply paſſion; while all paſſive verbs on the other hand imply action. Hence the one may aſſume the form of the other without altering its nature. Thus, *ille amat parentes*, he loves his parents, is the ſame in ſenſe as *parentes amantur ab illo*, his parents are loved by him. The only difference is that, in the firſt inſtance, the agent is nominative, and the object accuſative: in the ſecond, the object, becoming the ſubject of the verb, is put in the nominative, and the agent in the ablative. An agent, while it acts, is acted upon. Every active verb, therefore, has the compound ſenſe of active and paſſive. Thus, in the above ſentence, *he loves his parents*, the firſt part, *he loves*, is active; the laſt, *loves his parents*, is paſſive. In the ſame ſentence, converted into the paſſive form, *his parents are loved by him:* the firſt part is paſſive, and the laſt active. In the infancy of language, the diſtinction of active and paſſive was in all probability not known. In Hebrew, the difference but imperfectly exiſts, and in the early periods of it probably did not exiſt at all. In Arabic, the only diſtinction which obtains, ariſes from the vowel points, a late invention, compared with the antiquity of that language. And in our own tongue the names of active and paſſive would have been unknown, if they had not been imported from the Greek and

Latin grammars. In Engliſh the paſſive form of the verb is expreſſed by the connecting verb *to be*, and the perfect participle; and in converting an active into a paſſive propoſition, we need only change the verb to its perfect participle, and ſubjoin it to the connecting verb in the ſame mood and tenſe, and annexing the agent with its correſpondent prepoſition in the ablative caſe. Thus, we worſhip God, becomes *God is worſhipped by us*. Hence it appears that verbs which are tranſitively active can be made paſſive, becauſe they have an object, which, in the paſſive form, is made the ſubject of diſcourſe; and that verbs intranſitively active cannot have a paſſive form, becauſe they have no object.

The paſſive voice, in all languages, is expreſſed by the connecting verb, and the perfect participle for its predicate; and it is curious to obſerve, that this combination is its origin in the Greek tongue, the ſubject of diſcourſe being combined with the perſonal pronouns in the dative caſe. Thus, οικος μοι, *houſe for me*, which do not, as before, coaleſce as a ſubject with an agent; but as a ſubject with the perſon to whom it belongs, and for whom it was intended. Hence their combination came to convey the idea *I am houſed*, *I am built*: for the auxiliary *am* ſerves only to aſſert that *houſed* or *built* belongs to the pronoun preceding it, and to cement their union in the mind as ſubject and predicate. In the ſame manner, if σοι, τοι, be annexed to the word οικος, we have οικος σοι, οικος τοι, *houſe for thee*, *houſe for him*. And theſe contractions, by ſlight changes, became οικιζομαι, οικιζεσαι, οικιζεται, *I am built*, *thou art built*, *he is built*.

A verb, if its operation paſs over to another thing, or if it have an object to expreſs the effect of that operation, may be called *tranſitive*; but if its influence do not paſs over, or if it have no object, it is *intranſitive*. Verbs, on the other hand, not expreſſing action, but *being*, *poſture*, *continuance*, and ſerving to aſſociate two things, as a ſubject and predicate, may with propriety be called *connecting* verbs. Of this claſs is *am*, with all its branches, or the correſponding verbs in Latin and Greek. And here it is proper to obſerve that verbs of motion came in all languages to ſignify *continuance*, *poſture*, and the like, becauſe we can meaſure *duration*, or even *reſt*, and privation of motion, only by ideas conſequent on motion. Thus, in our own tongue, "a diligent boy will *become* a learned man." "By thee diſpoſed into congenial ſoil, *ſtands* each attractive plant," *i. e. is diſpoſed*. So in Latin, "Quum placidum ventis *ſtaret* mare," when the ſea *ſtood* (*i. e. was* continued) tranquil from the winds. Veniet lenior, ſhe will come milder, *i. e.* will *be* or *become* milder. Vixiſſet immundus ſus, he would have lived, *i. e.* he would have become a filthy pig. Ego incedo regina, I walk a queen, *i. e.* I am a queen. Theocritus, ſpeaking of the iraſcibility of *Pan*, writes Και οι αει δριμεια χολα ποτι ῥινι καθηται, keen anger always *ſits* in his noſe, *i. e.* the breath of anger always continues in his noſtrils, or, he is ever iraſcible. On this principle it is that εχω, in Greek, as implying continuance or poſture, came to have the ſenſe of *am*—καλως εχω, *I am well*; and that εω, *I am*, and ιω, *I go*, were originally the ſame. And in Latin *eaco* became, for a ſimilar reaſon, into *eſceo*, which occurs in Lucretius in the ſenſe of *eſt*. From *exire* the Italians have derived *uſcire*, to go out, end, and *uſcio*, *exitus*, a door, or avenue. Hence we have derived *to uſher*. The Italian ſtato, *been*, owes its derivation from *ſto*, to the ſame mode of thinking. All verbs, then, are either tranſitive or intranſitive, or connecting verbs. And this diviſion appears to us obvious, uſeful, and philoſophical.

The properties of verbs are mood, tenſe, number, and perſon. On theſe properties, as they are diſcuſſed in all grammars, (ſee L. Murray's valuable Grammar of the Engliſh Tongue: Dr. Crombie on Etymology and Syntax; Dr. Prieſtley's Philoſophical Grammar, and particularly Mr. Pickbourn's excellent Diſſertation on the Engliſh Verb,) we ſhall content ourſelves with a few obſervations. Mr. Tooke, vol. ii. 473, ſays that mood, tenſe, number and perſon are no parts of the verb. But this opinion will appear to be erroneous, if we reflect on the manner in which verbs are derived from nouns. For the perſonal pronouns in each number enter into the compoſition of a verb in the ancient languages, where it is diſtinguiſhed by perſonal termination; though we acknowledge the aſſertion to be juſt in Engliſh, where the verb is known only from the annexed pronoun, or its connection with the agent and object. Again, if we reflect on a verb in its formation, we perceive it to contain an idea, the reſult of obſervation and experience, which, as *paſt*, is *certain*, *abſolute*, and *unconditional*. This certain, abſolute, and unconditional form is eſſential to the verb, and it conſtitutes that *mode* or *manner* called the indicative mood. As the indicative mood reſpects the paſt time; ſo the ſubjunctive, in reſpect to it, regards the future. And as all future events, at leaſt with reſpect to man, are *uncertain*, *relative*, and *conditional*, all verbs, expreſſing an uncertain, relative, or conditional ſenſe, are in the *ſubjunctive*, ſo called from its being *ſubjoined* to a verb in the indicative. All verbs, moreover, expreſſing an *end* or *intention*, as being from their nature uncertain, are uſed in the ſubjunctive; and for this reaſon it might be called the *final mood*. In this view it has a cloſe affinity to the *infinitive*, which, as we have already obſerved, is only an abſtract noun with the prepoſition *to*, denoting the end or object to which the preceding verb is directed. Accordingly, they may be ſubſtituted one for the other, in all inſtances. Thus, *I deſire to learn*; I deſire, the object of my deſire being learning; I deſire that I ſhould learn; I deſire, *that* being my end, I ſhould learn. Hence it follows that the ſubjunctive mood is not eſſential to language, and for this reaſon it does not exiſt in Hebrew and ſome other tongues. As a command is neceſſarily given in the time *now*, the imperative has no tenſe but the preſent, nor can it, in ſtrict propriety, have a firſt perſon, ſingular or plural; becauſe it would be abſurd in a perſon to command himſelf. *Let me love*, then, is not the *firſt* but the *ſecond* perſon, as may appear by ſubſtituting *permit* for its equivalent *let*, *Permit thou me to love*.

Finally, if we reflect on the verb in its element, we ſhall find that *time paſt* is eſſential to it, becauſe the converſion of a noun and the annexed pronoun into a verb is in conſequence of paſt experience or obſervation. But as preſent feeling or conſciouſneſs coaleſces with our reflection on the paſt, the verb, which owes its exiſtence to the paſt, comes to ſignify alſo the preſent. And this is the reaſon why in Hebrew, the moſt ancient language, the ſame form of the verb expreſſes the paſt and the preſent time; and this, too, appears to be the reaſon why in Engliſh and all other languages a verb in the preſent tenſe is often uſed, in an extended ſenſe, to comprehend all time, preſent and paſt. As, *the ſun riſes every day*; *birds fly*; *truth is always one*. In theſe and ſimilar inſtances no reference is made to the *future*; unleſs the future, by aſſociation, inſenſibly in our minds coaleſces with the paſt. But men ſoon became ſenſible of the neceſſity of limiting the verb in regard to time. They ſoon acquired a diſtinct notion of the three diviſions of time into preſent, paſt, and future; and in order to vary the terminations of the verb, ſo as to correſpond to theſe diviſions, nothing more was neceſſary than to follow the impulſe of aſſociation acting on accidental corruptions. Hence the origin of tenſes, which, as the word implies, are the *extenſion* of the verb by diſtinguiſhing terminations to expreſs the diviſions of time. And here we cannot help obſerving, how improper it is to call tenſes, and ſimilar contrivances, *abbreviations,* (as is done by Mr. Tooke,) a name, the very reverſe of what a tenſe purports to be. The formation of the tenſes in Hebrew is worthy of attention, and ſhews that the human mind, under the influence of a rational law, without perhaps the expreſs exertion of reaſon, may produce a contrivance for its beauty and ſimplicity truly admirable. In that language the diſtinguiſhing termination is the perſonal pronoun, annexed or prefixed. Now, ſuppoſe תִי, *ti,* a fragment of the firſt perſonal pronoun, to mean *I.* It will alſo become a natural index of the time now, whenever the ſpeaker uſes it in connection with a verb, becauſe he meaſures the preſent moment by the uſe of it, or by reflecting on himſelf when uſing it. This being the caſe, a verb *preceding* TI will be a paſt verb, by pointing, as it were, the attention backward, as *Pegod-ti, viſited I,* or *I viſited;* while a verb *ſucceeding* the ſame particle expreſſes the *future* time: the pronoun, being the index of the preſent time, points now the attention forward, as *ti-pegod, I viſit,* (meaning *I will viſit).* But for *tia,* the other fragment of the perſonal pronoun, is uſed *apegod.* In modern languages which have no diſtinguiſhing terminations, the notification of time future is but an inference drawn from verbs of volition or deſire, in conſequence of the conſtant aſſociation of the object of that volition or deſire with time to come: as *I will learn,* which meant, at firſt, *I am reſolved to learn,* and then the time when the reſolution is to be performed. Thus *ſhall* and *will,* which are the Hebrew שאל, *ſhaal,* and the Greek βουλω, *volo,* in a ſecondary ſenſe become indices of time to come. It is here of importance to remark, that though *ſhall, will,* with *do, may, have,* &c. are called auxiliaries, they are ſtill leading verbs, and govern thoſe, which they are ſuppoſed to ſubſerve, in the infinitive mood.

The Greek has been repreſented as very like the Shanſcrit; but in truth, the old Æolic dialect, whence the Latin is derived, claims a much cloſer affinity with the great Indian language; and in that dialect of it which is ſpoken in Bengal, the mark of the future tenſe is *bo.* Thus *hoibo, I ſhall be,* is the future of *hona;* juſt ſo is the Latin *amabo,* the future of *amo; abo* being originally *awo,* a form of the verb denoting *cauſative,* and thence *ſucceſſion,* or tranſition in regard to time. Mr. Tooke, indeed, in his uſual manner, ſuppoſes *amabo* to be an abbreviation of *amaboule, amaboul, amabo,* ſee vol. ii. 434. But the primary ſenſe of βουλω is *to will,* or *deliberate;* and upon the ſame principle that this verb became an index of future time, any other verb or form of a verb would be made an index of it by aſſociating its object with futurity. The ideas which this grammarian had of language are altogether mechanical; and by rejecting the principle of mind, while continually hunting after blind mechaniſm, he ſeems to us not to have ſuſtained the character of a philoſopher in explaining its phenomena.

The Origin and Properties of Participles.

Mr. Harris's account of participles is as follows: Every complete verb is expreſſive of an *attribute of time,* and of *an aſſertion.* Now if we take away the aſſertion, and thus deſtroy the verb, there will remain the attribute and the time, which make the eſſence of a *participle,* p. 184. This ſtatement has conciſeneſs and ſimplicity to recommend it, though we do not regard it as correct. Mr. Tooke gives us the following account of participles. "This ſort of word is by no means the ſame with a *noun adjective.* The participle has all that a noun adjective has; and for the ſame reaſon, *viz.* for the purpoſe of *adjection.* But it has likewiſe ſomething more than a noun adjective has; becauſe the *verb* has ſomething more than the noun. And that ſomething more (as Perizonius proceeds to aſſert) is not only the adſignification of time, for every verb has a ſignification of its own, diſtinct from *manner* and *time.* And language has as much occaſion to *adjective* the diſtinct ſignification of the verb, and to adjective alſo the *mood,* as it has to adjective the time. And it has, therefore, *adjectived* all three—the diſtinct ſignification of the ſimple verb, and the verb with its moods, and the verb with its tenſes. I ſhall at preſent notice only ſix of theſe verb-adjectives, which we now employ in Engliſh, *viz.* the ſimple verb, itſelf adjective; two adjective tenſes, and three adjective-moods.

"We had formerly in Engliſh only the ſimple *verb-adjective,* and the paſt tenſe adjective. In addition to theſe two, we have now the convenience of four others, which I muſt call the *potential mood active adjective;* the potential mood paſſive adjective; the official mood paſſive adjective; and the future tenſe active adjective. As the noun adjective always ſignifies *all* that the unadjectived noun ſignifies, and no more, except the circumſtances of adjection; ſo muſt the verb adjective ſignify *all* that the unadjectived verb ſignifies, and no more, except the circumſtance of adjection. But it has been uſual to ſuppoſe, that with the indicative mood, as it is called, is conjoined alſo the ſignification of the preſent time, and, therefore, to call it the indicative mood preſent tenſe. And if it were ſo, then indeed the word we are conſidering, beſides the ſignification of the verb, muſt likewiſe adſignify ſome manner and the preſent time; for it would be then the preſent tenſe adjective as well as the indicative mood adjective. But I deny it to be either. I deny that the preſent time, or any time, or any *manner,* is ſignified by that which is called improperly the indicative mood preſent tenſe. And, therefore, its proper name is merely the verb—*indicative,* if you pleaſe, *i. e. indicative* of being merely a verb."

Our readers, we are ſure, will not be able to peruſe this account without ſurpriſe; and we ſhall endeavour to ſet it aſide by a more ſimple and rational account of the participle. The *preſent participle* denotes the operation of a verb without regard to any agent; the *perfect participle* denotes the ſtate, power, or habit, generated by that operation in a perſon or thing which is the object of it. If this ſtatement be juſt, the participle in its genuine ſtate is rather a verbal *noun* than a verbal *adjective,* and has a cloſe affinity to the infinitive mood. Hence, we can account for the origin and uſe of the participle. The Hebrew, and more eſpecially the Arabic, form their verbal nouns by what is called *nunnation,* or the ſyllable *on* added to the verb; and this is the Greek participle in ων, which the Latins have converted into *ens;* but which we, by giving *n* a naſal ſound, have corrupted into *ing.*

As the participle is a verbal noun, we ſee the reaſon why in all languages it is either uſed as a noun, or gives birth to various claſſes of abſtract nouns. The preſent participle, as expreſſing an operation, naturally coaleſces with an agent, and this is the reaſon why in Hebrew, in Greek, and ſometimes in Latin, it denotes a doer, or a perſon who acts; as ὁ γραφων, *he writing, the writer; amans, he loving, the lover.* From its facility to coaleſce with a noun, the participle loſes its nominal character, and becomes an *adjective;* and as it denotes an active quality, or a power in energy, it forms, with the connecting verb *to be,* the three active compound tenſes—*I am writing—he was writing—they ſhall be writing.*

Farther, as all operations are in *time,* and we acquire the idea of time preſent by reflecting on ſucceſſive operations, the preſent participle implies *time* unlimited, and in its aſſociated

ciated effect *time preſent, i. e.* time preſent, not abſolute, but *relative.* Thus, *I am writing, i. e.* I am *now* writing; I was writing, *i. e.* I was writing *at the time then* preſent. And, in general, the participle is defined by the concomitant verb in the ſentence which may be either preſent, paſt, or future. If the verb be paſt, it marks the paſt time as then preſent; if future, it marks the future as hereafter preſent. And thus is refuted the opinion of Mr. Tooke, that there is no *adſignation of time* in the preſent participle. But as he may pronounce this argument a mere evaſion, I will illuſtrate it by a parallel inſtance in Greek. The ſubjunctive verb τυψω, τυψῃς, &c. is thought to be the *firſt aoriſt;* but it is really the *firſt future,* and this is proved by its ſignification as well as by analogy, for in all inſtances this expreſſes a *future* time, not indeed abſolutely ſo, but future in regard to another verb connected with it in the ſentence. For example, "and they aſked him, ſaying, if it be lawful to heal on the ſabbath-day, that they might accuſe him," ἱνα κατηγορησωσιν. To accuſe him was their end in aſking, and in regard to that act was *future,* though now long paſt. Finally, things which act in conſequence of acting, acquire a *diſpoſition* to act, juſt as bodies when moved have a tendency to move. Repetition, moreover, imparts to the acting quality additional ſtrength, protenſion, and permanence. To expreſs it with the propenſity and vigour thus attained by uſe the participial termination ων in Greek is added to a noun or to an adjective, which, as receiving an additional meaning, is called an *augmentative.* Thus, ειρων, *ſpeaking,* means alſo one who is prone to ſpeak, which is the character of the ſcoffer or diſſembler; απατων, *deceiving,* one given to deception, a great deceiver; κακος κακιων, *more wicked, increaſing in wickedneſs.* And from this the Italians have derived one way of augmenting their nouns. Hence, our *ſaloon,* (a great hall), *balloon,* and, perhaps, *poltroon,* the augmentative of *paltry.*

The perfect, or paſt participle, is certainly derived, as Mr. Tooke repreſents, from the paſt tenſe.—*Amavit, amavitus, amatus;—docuit, docuitus, doctus;—legit, legitus, legtus, lectus;—audivit, audivitus, auditus. Us,* which is the Greek ος, is added to the third perſon as the analogical termination of nouns, to ſhew that the verb is now abſtracted into a verbal noun, denoting the effect of the action. Accordingly *amatus, doctus, lectus, auditus,* and the like, are every one either abſtract nouns of the fourth declenſion, or verbal adjectives coaleſcing with another noun. And here we ſhall quote a paſſage from the Encyclopædia Britannica, (p. 86.) to ſhew into what errors grammarians have fallen, by not having attended to the *nominal character* of the participle: "From theſe obſervations and examples," ſays the writer, "we ſhall be able to underſtand the two uſes of the adjective. It is either employed to *reſtrict* or *modify* a *general term;* or the abſtract ſubſtantive contained in the adjective is modified by the noun with which, in the concrete or adjective form, that abſtract ſubſtantive is joined. The firſt may be called the *direct,* the ſecond the *inverſe* acceptation of adjectives. Livy, ſpeaking of the abolition of the regal authority at Rome, ſays; "Regnatum eſt Romæ ab urbe *condita* ad *liberatam* annos ducentos quadraginta quatuor:" Monarchy ſubſiſted at Rome, *not* from the city built (which would convey no meaning,) but *from the building* of the city, to its deliverance. Both the participles *condita* and *liberatam* are here uſed inverſely, *i. e.* the abſtract ſubſtantives contained in *condita* and *liberatam* are modified and reſtricted by the ſubſtantives *urbe* and *urbem,* with which they unite. Again, Ovid, ſpeaking of the conteſt between Ajax and Ulyſſes for the arms of Achilles, has theſe lines:

> "Qui licet eloquio fidum quoque Neſtora vincat
> Haud tamen efficiet, deſertum ut Neſtora crimen
> Nullum eſſe reor."

Here alſo the adjective or participle *deſertum* is taken inverſely, and the general notion of *deſertion* contained in it is modified or rendered particular, by being joined with the ſubſtantive *Neſtora.* The meaning of the paſſage is, "I will never be induced to believe, that the deſertion of Neſtor was not a crime." Were *deſertum* to be taken directly as an adjective, modifying its ſubſtantive, the ſentence muſt be tranſlated, "I cannot believe that Neſtor deſerted was not a crime." But it is evident that this is nonſenſe; as Neſtor, whether deſerted or not deſerted, could not be a crime."

This writer was led by Mr. H. Tooke to conſider every adjective as a noun in its nature: he then makes a diſcovery in which he ſeemingly blames himſelf, which is this: inſtead of the adjective qualifying its noun; the noun inverſely qualifies its adjective! This able writer would not have uſed this language, if he had truſted to his own underſtanding, and had not allowed himſelf to be miſled by his guide. The participles *condita* and *liberatam,* though they here coaleſce with another noun, ſtill retain their original character of a ſubſtantive, and the hiſtorian has apprized his readers of this character by the *collocation,* where *condita* is rendered prominent and emphatic by ſucceeding the qualified *urbe.* The ſame obſervation applies to *deſertum Neſtora,* which is equivalent to *deſertionem Neſtoris.*

As the paſt participle expreſſes the effect of an operation, it has been called the *paſſive participle;* but when the ſubject of an operation is a moral agent, that effect is *habit,* or a voluntary principle of action. And thus it is, that the perfect participle often expreſſes or implies action; as, *admiratus, having admired; locutus, having ſpoken.* Sometimes in Greek and Latin it conveys a reflex ſenſe; as *ſtratus membra, having proſtrated his limbs;* πεπιστευμενος ευαγγελιον, *having the goſpel entruſted to me.* And laſtly, as the perfect participle is derived from a paſt verb, and, as it ſignifies an effect already produced, it points to time paſt; nevertheleſs, as that effect is a habit or power capable of action, it implies time preſent, and thus the paſt participle, comprehending both times, anſwers to the denomination of *perfect preſent.*

The Origin and Properties of Prepoſitions.

Mr. Harris defines a prepoſition to be a part of ſpeech, devoid itſelf of ſignification, but ſo formed, as to unite two words that are ſignificant, and refuſe to coaleſce or unite of themſelves. This definition is undoubtedly erroneous, and has been juſtly cenſured by Mr. H. Tooke. We venture, however, to affirm, that the account given by the laſt-mentioned writer, is by no means ſuch as a philoſopher, who accurately underſtood his ſubject, would give of prepoſitions. "As the neceſſity, ſays he, vol. i. p. 319, of the article, or of ſome equivalent, follows from the impoſſibility of having in language a diſtinct name or *particular term* for each particular individual idea; ſo does the neceſſity of the *prepoſition,* (or of ſome equivalent invention) follow from the impoſſibility of having in language a diſtinct complex term for each different *collection of ideas,* which we may have occaſion to put together in diſcourſe. The addition or ſubtraction of any one idea, to or from a collection, makes it a different collection: and if there were degrees of impoſſibility, it is ſtill more impoſſible to uſe in language a different and diſtinct complex term for each different and diſtinct collection of ideas, than it is to uſe a diſtinct particular term for each particular and individual idea. To ſupply, therefore, the place of the complex terms which are wanting in a language, is the prepoſition employed, by whoſe aid complex terms are prevented from being infinite or too numerous, and are uſed only for thoſe collections of ideas which we have moſt frequently occaſion to mention in diſcourſe. And this is obtained in the moſt ſimple manner in the world. For having occaſion, in communication, to mention a collection of ideas, for which there is no one ſingle complex term in the language, we either take that complex term which includes the greateſt number, though not *all* of the ideas we would communicate, or elſe we take that complex term which includes all, and the feweſt *more* than thoſe we would communicate; and then, by the help of the prepoſition, we either make up the deficiency in the one caſe, or retrench the ſuperfluity in the other. For inſtance, " A houſe *with* a party wall," " A houſe *without* a party wall." In the firſt inſtance, the complex term is deficient. The prepoſition directs to add what is wanting. In the ſecond inſtance, the complex term is redundant. The prepoſition directs to take away what is wanting."

Now this ſtatement appears to us to be more properly deſcriptive of *conjunctions* than of prepoſitions, it being made altogether in reference to *with,* which has, in the above inſtance, only a *conjunctive* ſenſe; as, a houſe *and* a party wall, *i. e.* a houſe *add* a party wall, or, as Mr. Tooke explains, *with* a houſe *join* a party wall. The following we deem a more juſt repreſentation. Prepoſitions expreſs the relations of things; and, as our ideas of relations are aſſociated effects, ariſing from our ideas of things, ſo the words expreſſing relations are borrowed from the things related, that is, prepoſitions originated in nouns and verbs. But we have ſeen, that the relations of things are alſo expreſſed by *caſes.* Caſes, therefore, and prepoſitions, have the ſame meaning; the former, indeed, being no other than the latter combining with nouns, and thus giving them different terminations, bearing diſtinct ſenſes. The three leading relations we have farther ſeen expreſſed by caſes, are *beginning, inſtrument* or *medium,* and *end.* Thoſe prepoſitions, then, which ſignify *beginning,* require the noun ſucceeding them to be in the *original* ſtate or poſition, or, agreeably to the uſual language, govern the *genitive* caſe. Thoſe ſignifying *inſtrument* or *medium* govern their dependent nouns in the *inſtrumental* or *medial,* or, as it is commonly called, the *ablative* caſe; while thoſe denoting the object or end to which an action or motion relates, to which it tends, and in which it terminates, have their governed nouns in the *final* or *dative* caſe.

We now proceed to aſcertain the meaning of the leading prepoſitions, by deducing them from their origin. And we ſhall find that Mr. Tooke, as his ideas are unſatisfactory and unappropriate in regard to the uſe of prepoſitions, is miſtaken in almoſt every inſtance, in reſpect to the ſources in which they originated. And here we muſt premiſe, that our ideas of beginning, medium, and end, are ſo palpable and diſtinct, and ſo eſſential to diſtinctneſs in our other conceptions, that they are nearly *coeval* with our ideas of things and of motions; and conſequently muſt have exiſted in the language of men, as ſoon as it reached a form deſerving of that name. And as we maintain, that all the varieties of human ſpeech which now exiſt, or have ever exiſted, are but branches propagated by various cauſes, (like the human race itſelf,) from a few parental ſtems in the one primeval language of mankind; ſo we maintain, that moſt prepoſitions in different languages, are but the ſame original words, differently corrupted, agreeably to the genius of the people who borrowed them from their anceſtors; and that the Engliſh prepoſitions, in particular, are antecedent to Anglo-Saxon and Gothic corruptions, or, as Mr. Tooke would ſay, *abbreviations,* and originated in oriental words, derived in many inſtances through the medium of Greek and Latin. The derivation of the conjunctions and prepoſitions is, indeed, the moſt ſpecious part of Mr. Tooke's ſyſtem; and not only in his own opinion, but in the opinion of the public, he lies ſo ſtrongly fortified, that no adverſary can diſlodge him. We ſhall, however make an attempt for this purpoſe.

" I imagine, ſays he, p. 367, that *of* (in the Gothic and Anglo-Saxon *af*) is a fragment of the Gothic and Anglo-Saxon *afara* or *afora, poſteritas, offspring,* that it is a noun ſubſtantive, and means always *conſequence, offspring, ſucceſſion,* or *follower.*" Now as to *afora* it is nothing but the Greek φορον, *produce,* from φερω, and the meaning of *of* is quite the reverſe of *conſequence,* &c. Thus, in the phraſe *rays of the ſun, of* points to the ſun as the origin of rays. It means, therefore, *ſource, origin,* and its derivation is אב, *ab,* root, ſtem, απο, αφ, *ab.* The genitive caſe, which correſponds to *of,* further proves this, *Solis radii,* where *is,* annexed to *ſol,* ſurely does not mean that the ſun is a conſequence of the rays, but that it is the origin of the rays. The ſource or cauſe of a thing is before that thing in the order of nature. Hence, according to the uſual arrangement in Latin, the noun in the genitive is put *before* that which proceeded from it, and this is the reaſon why in Engliſh we always ſay *father's houſe,* (*father is houſe,*) and never *houſe father's,* having copied not only the genitive termination of the third declenſion, but alſo the collocation of the noun affected by it. Moreover, not *of* but *after* came from the Gothic *afara,* becauſe this, meaning *offspring,* came alſo to denote *ſucceſſion,* or that which comes after thoſe who gave it birth. And in the Gothic it is uſed as a prepoſition ſignifying *paſt, after,* where the *t* is introduced to humour the pronunciation, as δ is inſerted in ανδρος for ανερος, or ανρος.

As *of* means beginning, it has the ſame ſenſe with *from*: which laſt Mr. Tooke derives from the Gothic and Anglo-Saxon *frum,* meaning *firſt, beginning.* This may be admitted. But whence did *frum* originate? The Latins, it is well known, converted the Greek termination ν into *m.* Thus the accuſative ιν became *im* or *em*; the genitive plural ων, *um,* and the neuter ending ον, is alſo *um* in Latin. On this principle πριν is the parent of *primus.* This laſt the Goths of Wallachia, where, as Michaelis obſerves, a Latin colony had been eſtabliſhed, and whoſe language, after thus blending with the Latin, is the only ſpecimen of the Gothic preſerved in modern days, have borrowed and corrupted in the form of *frum,* which retains the original ſenſe of *initium, principium.* But we are not yet arrived at the origin of the word. The Arabic פרע, *phra,* among other meanings, denotes *the head of a family*; which being rendered more general and abſtract, gave birth to the Greek πριν, πρὶν, to the Latin *præ,* to *fra* in the Icelandic, Norſe, Daniſh, Swediſh, to *fry* in Friſch, and *frae* in Scotch. And thus the Arabic origin of the word accounts for the different forms of *from, fra, fry, frae,* in the Northern dialects, the firſt being derived through the medium of Greek and Latin; the others immediately from Aſia. Mr. Tooke happens to be right in the meaning of *from,* merely becauſe the Gothic corruption of *frum* has correctly retained the original ſenſe of *primus.* He thus illuſtrates its ſignification. Figs came from Turkey; lamp falls from cieling; lamp hangs from cieling. Figs came, beginning Turkey, that is, Turkey the place of beginning to come. Lamp falls, beginning cieling; cieling the place of beginning to fall. Lamp hangs, beginning ceiling; ceiling the place of beginning to hang. This explanation is rational and juſt: but when he adds came is a complex term for one ſpecies of motion; falls is a complex term for another ſpecies of motion; hangs is a complex term for a ſpecies of attachment, though very true, this is nothing to the purpoſe. *Came, falls, hangs,* imply each motion or direction, and *from* points to the origin of the motion or direction in each, without any reference whatever to their peculiar meaning.

To the prepoſitions *of* and *from*, ſtand oppoſed *to*, *till*, and *for*. Mr. Tooke might, with equal propriety, derive *to* from his own name, as derive it from the Gothic *taugan*, to act, which is but the Greek τευχω, *to fabricate.* Equally abſurd is it to ſay, that the Latin *ad* is from *actum.* The parent word, as we have ſeen, is the Arabic אתא, *ata*, to move to a thing. In Celtic, the word has preſerved its original form *(atto,)* in the exact ſenſe of *to.* But in Perſian, loſing the initial vowel, it became *taa*; whereas, in Latin, retaining the firſt and dropping the laſt, it exiſts under the form of *ad*, and in Engliſh under that of *at*. *To* and *at* have a ſignification correſponding to their kindred origin, the former denoting the object of motion, the latter coaleſcence with that object after its reaching it. "That *till* ſhould be oppoſed to *from*, ſays he, only when we are talking of time, and upon no other occaſion, is evident for this reaſon, *viz.* that *till* is a word compounded of *to* and *while*, *i. e. time.* And you will obſerve, that the coaleſcence of theſe two words *to*, *while*, took place in the language long before the preſent wanton and ſuperfluous uſe of the article *the*, which, by the prevailing cuſtom of modern ſpeech, is now interpoſed. So that when we ſay, "From morn *till* night," it is no more than if we ſaid, "From morn to *time* night." When we ſay, "From morn *to* night," the word time is omitted as unneceſſary. So we might ſay, "From Turkey to the place called England, or to *place* England," p. 363. But *while*, or, as it is in the Anglo-Saxon, *hwile*, does not mean time but a *period*, or *revolution* of time, ſuch as a day, week, &c. and is derived from the Hebrew גול, *gul* or *geel*, to revolve, and *year*, or, as our anceſtors ſpelled it, *gear*, is derived from גור, *gure*, or in Greek γυρεω. The Hebrew *geel* is alſo the parent of our *wheel. To* points to a final object either in place or time, while *till*, in ſtrict propriety, is applied to time only, and is derived from τελλω, *to riſe*, and was at firſt expreſſive of the riſing ſun. Thus, "I will wait *till* morning," *i.e.* I will wait the riſing morning. As *till* denotes time, riſing, or alternation of time, the word is always underſtood to be followed by ſome change implied in the context, but never expreſſed: thus, "We are always inſenſible of a bleſſing, *till* (or *until*) we loſe it," then, "we *are* ſenſible of it," is a clauſe implied. "They will ſtay *till* morning;" and they will then depart, is to be underſtood. *Till* exiſts in the Cimbric language, and this is an additional proof, that the uncouth compoſite to *while* is a mere fiction of Mr. Tooke.

Mr. Tooke takes *for* to ſignify *cauſe*, as oppoſed to *of*, ſignifying conſequence, from the Gothic ſubſtantive *ferina*, *a cauſe*, p. 367. He thus illuſtrates them, I am ſick *of* my huſband, and *for* my gallant. Love makes her ſick *of* and ſick *for*. Here *of* and *for* ſeem almoſt placed in oppoſition. At leaſt their effects in the ſentence are moſt evidently different: for by the help of theſe two prepoſitions alone, and without the aſſiſtance of any other words, ſhe expreſſes the two contrary affections of loathing and deſire. Her diſguſt was the offspring of her huſband, proceeded from her huſband. Her gallant was the *cauſe* of her love. But if her diſguſt proceeded from her huſband, he was the *cauſe* of her diſguſt: and *of* and *for*, inſtead of being oppoſed to each other, as they certainly are, mean juſt the ſame thing, namely, *cauſe*, and not *cauſe* and *conſequence.* But in truth, the matter is juſt the reverſe of what our grammarian repreſents. *Of* means *cauſe* or *origin*, and *for* means *conſequence* or *end.* She is ſick of her huſband—ſhe is ſick, her huſband is the ſource of it—ſhe is ſick for her gallant, and the object to which ſhe looks with deſire is her gallant. Accordingly, *for* always ſuppoſes the attention not directed *backwards*, as to the cauſe, but *forwards*, as to ſome end; and its etymology is this, περαω, to *paſs* over, περ, or *per*, the medium of paſſing to an object; the French *pour*, *for*, the object or end to which paſſage is made. Johnſon gives *for* forty-ſix different meanings. But there is not one inſtance in which it does not bear a ſenſe deducible from its primary ſignification of *end* or *object.* Thus, Chriſt died *for* us; Chriſt died, *us*, (*i.e.* our redemption,) being the end or object of his death. To fight *for* the public good; to fight, the public good being the end or object of fighting. He does all things *for* the love of virtue. He does all things, the love of virtue being the end or motive of all his actions, and ſo in all other inſtances.

By (in the Anglo-Saxon *bi*, *be*, big) is the imperative of *byth* of the Anglo-Saxon verb *beon*, to be. And our anceſtors wrote it indifferently *be* or *by*. So then, according to this, our auxiliary *be* and the prepoſition *by* are of the ſame origin: and what analogy in the name of common ſenſe is there between them, excepting the accidental reſemblance of ſound. Let us apply this etymology to the ſolution of ſome example, "He was ſlain *by* the ſword," *i. e.* he was ſlain *be* a ſword, or, "let a ſword be." We might aſk let a ſword be what? Mr. Tooke has anticipated the queſtion by ſaying this prepoſition is frequently, but not always, uſed with an abbreviation of conſtruction: ſubauditur, *inſtrument*, *cauſe*, *agent*, &c. Really it appears to us ſurpriſing, that a man of taſte and underſtanding ſhould write thus. In Hebrew בא, *baa*, is *to paſs*, and is the parent of βαω in Greek. In Arabic and Perſian it became a prepoſition, ſignifying the medium of motion. In this ſenſe it gave birth alſo to the Latin *via* and to the Engliſh *way*, *bye*, and alſo to the Anglo-Saxon prepoſition *bi* or *be*, and the Engliſh *by*, which laſt was uſed by our old writers to ſignify the interval of time during which motion is continued; as, "By ſo long a time," *i. e.* for ſo long a time—By his life. *i. e.* during his life.

Then it came to ſignify the medium or inſtrument by which any action in general was performed. He was ſlain *by* the ſword—He was ſlain, the ſword being the medium or inſtrument of his ſlaughter. The derivation of *with* from *wyrthan* is no leſs abſurd. What has *with* to do with *wyr*, or, as we have it, *were*? The parent of this verb, which ſignifies *to exiſt*, is the Hebrew אור, *awar*, *light*, *air*, the medium of exiſtence. The Greek μητα, denoting *connection*, *concomitance*, *inſtrumentality*, has paſſed into the Anglo-Saxon in the form of *mid*, where it is corrupted into *with*, and exiſts in the ſame ſenſe in both forms. The letters *m*, *v*, *w*, are of the ſame organs, and often change one for another. Many Greek words are borrowed from the Hebrew, by changing מ into β; as משל, *maſal*, is βασιλευω, *to rule*; and all the Welſh words borrowed from Latin have *m* corrupted into *v*, *arma arve*; *mare voer*; *me ve.* Inſtances of this ſpecies of corruption occur in Anglo-Saxon and Gothic. Thus, the Gothic *weis* is the Greek ἡμεις: and hence the Anglo-Saxon, and the Engliſh *we*. Even *withan*, from which Mr. Tooke alſo derives *with*, is only the Latin *mitto*, *to ſeat*, *to put.* And not *withan*, as he ſays, but *ga withan* ſignifies *to join* or *put together.*

"The Engliſh prepoſition *through*, ſays our author, is no other than the Gothic ſubſtantive *daura*, or the Teutonic ſubſtantive *thurub*, and like them means *door*, *gate*, *paſſage*, p. 334." And he adds in the next paſſage, "After having ſeen in what manner the ſubſtantive *houſe* became a prepoſition in the French, you will not wonder to ſee *door* become a prepoſition in the Engliſh; and though in the firſt inſtance it was more eaſy for you to ſee the nature of the French *chez*, becauſe having no prepoſition correſponding to it in Engliſh; yet I am perſuaded you will not charge this to me as a fantaſtical or far-fetched etymology, when I have placed before you at one view the words employed to ſignify the ſame idea in thoſe languages to which our's has the neareſt affinity." After doing this, he adds, "Though it is not in Aſia or its confines that we are to ſeek for the origin of this part of our language, yet is it worth noticing here, that the Greek, to which the Gothic has in many particulars a conſiderable reſemblance, employs the word Θυρα for *door.*" All this is very ſpecious, and being confidently advanced, it has the aſpect of truth, though it be miſrepreſentation. The prepoſition *through* exiſts, as Mr. Tooke has ſhewn, in all the collateral languages; and it may be obſerved, what he has not, that there is a guttural annexed to the word *in all.* Thus in Engliſh *through*, Anglo-Saxon *thurub* or *thurb*, Gothic *therb*, German *durch*, Teutonic *duruc* or *durub*, &c. This uniformity in retaining a guttural, ſhews that a guttural was an original part of the word. And it is no other than the Hebrew דרך, *dark, road, paſſage,* which has given birth not only to this prepoſition, but to a multitude of other words in all languages. He came *through* Greece, he came, Greece being the *road,* a *paſſage* of his coming. The genial ſun warms *through* the air; the genial ſun warms; the *medium* or *paſſage* by which it does this, is the air. We ſhall only add on this ſubject, that the prepoſitions *down, neath, beneath,* exiſt in the Arabic, with little or no variation, and in the ſame ſenſe; while *among* is the Perſian *mecan, in the midſt,* the ſame with the Celtic *mewn.* In the Hindooſtanic it is ſounded with a naſal guttural, as if written *meng*, and by the ſame analogy that *mid* became *amid*; *bove, above; bout, about; meng* became *among.* The correſponding word in Hebrew is בין, *bin* or *been,* which means *ſeparation, diſtinction,* an idea the very reverſe of that contained in *mengan, to mix,* from which Mr. Tooke derives it. From ſignifying *ſeparation,* it came to ſignify the *interval* between two things ſeparated, and hence the Hebrew *bin* (or written with the *nunnation binon*) is the parent of the Anglo-Saxon *binnon, between, within.* The Greek περθα, *to overturn,* is in Latin *verto, to turn,* which the Anglo-Saxons have further corrupted into *weard-an, to turn to.* Hence, in the form of *ward* it came to ſignify the object to which the attention is directed; as *eaſtward, i. e. eaſt proſpect.* We add only the genealogy of *over,* Anglo-Saxon *ofer*; Greek ὑπερ; Hebrew עבר, *ober, to paſs over.*

We have already obſerved, that Mr. Tooke's deſcription of the nature and uſe of prepoſitions belongs more properly to the conjunctions. But we ought rather to ſay that it belongs to neither. Prepoſitions expreſs the relation of things, and thoſe relations are the ſame, whether things or the complex names of things are few or many: and the neceſſity of prepoſitions ariſes not from the impoſſibility of having a diſtinct complex term for each different collection of ideas, but from the neceſſity of thoſe ideas we have of things and their operations. It is therefore utterly erroneous to ſay, that the prepoſition is employed to ſupply the place of complex terms. On the other hand, the conjunctions ſerve to propoſe or to compare our ideas, to combine or to ſeparate them: and this uſe is entirely independent of the number or variety of complex terms. If the complex terms of a language be few, they cannot be ſo few as not to need being ſeparated; and if they be ever ſo numerous, they cannot be ſo numerous as not to need being joined in compoſition. Indeed what Mr. Tooke ſays on this ſubject is indiſtinct, inappropriate, and even nugatory; though ſome ſubſequent grammarians have gravely copied his reaſoning as oracular wiſdom.

The prepoſitions and conjunctions in Engliſh exiſt in the Anglo-Saxon and Gothic. But this circumſtance Mr. Tooke has kept out of ſight. He knew it would appear ſtrange to deduce words of this kind from verbs and nouns in the parent tongue, while the very ſame words exiſted in that tongue coeval, and in many inſtances antecedent to the nouns and verbs repreſented to be their origin. But whence came thoſe conjunctions and prepoſitions to the northern language? We have anticipated this queſtion by proofs from fact. Theſe branches of the northern tongue, as the northern tongue itſelf has done, originated in the oriental languages. The ſtructure of thoſe languages is ſuch, that the verb is the leading part of ſpeech, and not only the ſubordinate parts, but even the noun is derived from it. This doctrine is inculcated and ſupported by the moſt extenſive and obvious analogies, and taught in the popular grammar, ſo that no learner, who has made any progreſs in them, can be ignorant of the true origin whence thoſe particles including adverbs, prepoſitions, and conjunctions, are derived. The verbs, from ſignifying in the Aſiatic dialects the *actions* of things, degenerated to expreſs the *relations* and *connections* of thoſe things; and with ſome neceſſary variations incidental to ſounds, paſſed into Greek, Latin, and other tongues, in the form of prepoſitions and conjunctions; and they were thence propagated, with ſtill farther corruptions, into the Gothic, Anglo-Saxon, and other European dialects. Loſing much of their primary forms, and changed in ſignification, European grammarians ſoon conſidered them as diſtinct parts of ſpeech. And much uncertainty, confuſion, and obſcurity, hung for ages on the ſubject, till Mr. Tooke roſe and diſſipated the miſt, by aſſerting their true origin to be nouns and verbs. This he acknowleges, or rather boaſts to have been a mere *conjecture* at firſt; and it has this ſingular fate, that, while the conjecture itſelf is perfectly juſt, almoſt every inſtance alleged to ſupport it is erroneous and futile. Having no acquaintance with the oriental tongues, and ſeemingly little acquaintance with Greek and Latin, but endowed with a powerful mind, as we conceive, under ſome wrong biaſſes, and actuated by a deſire of opening new paths of ſpeculation, he boldly imputes the dignity of an ancient and independent language to oral corruptions, chiefly made by a barbarous people, ſo late as the dark ages. On ſome of theſe corruptions he lays his hands, and holds them forth to the public as the parents of thoſe words which long exiſted antecedently to thoſe corruptions. This we believe to be a juſt repreſentation of the queſtion, and our readers will hence be able to appreciate the merits of his ſyſtem. The following is the table of genealogy, which he gives of the leading conjunctions.

If	are the imperatives of	Gif	of their reſpective verbs	Gifan, *to give*
An		An		Au-an, *to grant*
Unleſs		Onleſs		Onleſan, *to diſmiſs*
Eke		Eac		Eacan, *to add*
Yet		Get		Gettan, *to get*
Still		*Stell*		Stellan, *to put*
Elſe		Ales		Aleſan, *to diſmiſs*
Though		Daf		Dafian, *to allow*
Bŭt		Bot		Botan, *to boot*
Būt		Beutan		Beon-utan, *to be put*
Without		Wyrthatan		Anan-ad dare congeriem.
And		An-ad		

We will briefly examine theſe. Skinner, before Mr. H. Tooke, has derived *gif* from the Anglo-Saxon *giſan, dare;* and perhaps this very word is the foundation of his theory, though he has not mentioned (and he may have forgotten) the circumſtance which gave birth to his conjecture. It is, however, important to obſerve, that the uſe of *gif,* as a prepoſition, is not of a late origin: for the Anglo-Saxons uſed it in that ſenſe, and derived it in common with the verb *giſan* from the Hebrew, Arabic, and Perſian word כף, *kaph, the palm*

palm of the hand. Now the action of the hand is two-fold, *to give* or *to receive.* In the latter ſenſe it has paſſed into Latin, and produced *capio, cæpio,* and even *habeo,* meaning *to hold;* in the former it has given birth to the Anglo-Saxon verb *gif,* which ſignifies the action of the hand in imparting. Our word *keep* is apparently of the ſame origin, meaning *to hold.* Mr. Tooke obſerves, that *gin* is uſed in our Northern countries, and by the Scotch in the ſenſe of *if,* and he juſtly ſays, that it is only a contraction of the participle *given.*

An, uſed by old authors, means *if,* as in the following lines, quoted by Johnſon:

> "An honeſt mind and plain: he muſt ſpeak truth
> *An* they will take it ſo; if not, he's plain:"

That is, *if* they will take it ſo. This Mr. Tooke derives from *anan,* to grant, which is only the Latin *annuo, to aſſent to;* whereas *an* is the Arabic particle אן, *an,* which is pronounced as if written *in,* when meaning *if.* We borrowed it from the Gothic, where it is employed, as it is alſo in Latin, to mark an interrogation. The derivation of *unleſs,* or, as it was formerly written, *onles,* from *on-les,* ſeems at firſt ſight not to be diſputed. The application of the Anglo-Saxon *onles* does not appear forced; as Troy will be taken, *onles* the palladium be preſerved, *i. e.* Troy will be taken, diſmiſs the palladium be preſerved, or, diſmiſs that circumſtance, namely, the preſervation of the palladium, and Troy will be taken. And yet we are perſuaded that this is not the true interpretation of *unleſs.* Mr. Tooke is not fair in explaining the words from which he would derive this and other particles; but, in order to anſwer his own purpoſe, gives them a meaning which they really do not bear. *Onleſan* is interpreted by *lye, un-leeſe ſc. un-looſe, ſolvere,* and it has no other meaning: and in this ſenſe it is incapable of ſolving the difficulty.—"Troy will be taken, *unlooſed* the palladium be preſerved," which is hardly ſenſe. Mr. Tooke acknowledges that the Anglo-Saxon writers have not given us inſtances of *onles* in a conjunctive ſenſe: "but, inſtead of it," adds he, "they frequently employ *nymthe* or *nemthe,* which is evidently the imperative *nym* or *nem* of *nyman* or *neman,* to which is ſubjoined *the, i. e. that;* and *nymthe, take away that,* may very well ſupply the place of *onles the,* expreſſed or underſtood, *diſmiſs that.* But *nyman* ſignifies not merely *to take,* but *to take counſel,* it being derived from the Greek νομιζω, to *conſult* or *deliberate;* while the Latin *nempe* is νομω πω, *by law, by right, rightly, truly: leaſe* is a ſecurity by law, and *unleſs,* we conceive, is a corruption of *unleaſed, i. e. unprovided, unſecured.* Thus, Troy will be taken, *unleſs* the palladium be preſerved, *i. e.* it being unprovided, or it being not provided, that the palladium be preſerved; or, provided that the palladium be not preſerved, Troy will be taken. This author adds *les,* the imperative of *leſan,* which has the ſame meaning with *on-leſan,* is likewiſe uſed by old writers inſtead of *unleſs;* as, "But will not bide there *leſs* yourſelf do bring him." To this he ſubjoins, in a note, p. 173, "It is this ſame imperative *leſs,* placed at the end of nouns, and coaleſcing with them, which has given to our language ſuch adjectives as *hopeleſs, reſtleſs, deathleſs, motionleſs,* &c. *i. e.* diſmiſs hope, reſt, death, motion." But *les,* we think, which, though not in a comparative form, conveys a comparative idea, is the offspring of the Greek λις, (as *little* is of λιτος) both ſignifying *ſmall, ſlender.* From denoting ſomething minute, it came, as the Latin *minus,* to expreſs *negation.* On this principle, *a ſleepleſs night,* meant at firſt not abſolutely a night without ſleep, but a night having leſs ſleep than is neceſſary, or leſs than uſual, though in time it came to convey abſolutely a negative idea. *Hopeleſs* without hope; *bottomleſs,* having no bottom: and we appeal to our readers, whether this explanation be not more ſimple and natural than *diſmiſs the bottom.* If this derivation be juſt, *leſt* or *leaſt* is not the paſt participle *leſed* of *leſen,* to diſmiſs, but a contraction of *leſſeſt,* the analogical ſuperlative of *leſs,* and it means the leaſt degree of ſome conſequence that follows the preceding clauſe; as, "Let thoſe who ſtand take heed *leaſt* they fall;" which means, let thoſe who ſtand take heed; if not, they will fall, and that is the leaſt that may happen.

Eke, and, in the Latin *ac,* is ultimately derived from the Greek αεξω, or as it is in Latin *augeo,* to increaſe, though it may come more immediately from *eacan,* the Anglo-Saxon offspring of αεξω. An obſervation of Mr. Tooke goes certainly to prove the latter, if we can depend on its correctneſs. "In each language," ſays he, "where this imperative is uſed conjunctively, the conjunction varies juſt as the verb does. In Daniſh, the conjunction is *og,* and the verb *oger.* In Swediſh, the conjunction is *och,* and the verb *oka.* In Dutch, the conjunction is *ock,* from the verb *oecken.* In German, the conjunction is *auch,* from the verb *auchon.* In Gothic, the conjunction is *auk,* and the verb is *aukan.*" This example ſerves to ſhew how nearly allied theſe languages are one to another, and how a large portion of them is derived from the Greek and Latin.

Yet is aſſuredly the Anglo-Saxon *get* or *gut, adhuc, etiam,* though Mr. Tooke has referred it to the verb *to get.* This grammarian ſeems not to have ſufficiently ſtudied thoſe analogies by which the genius of a language is formed. The Anglo-Saxon, delighting in gutturals, forms many of its words by prefixing the particle *ge,* or the letter *g.* Thus, *gefryn, pridem,* is only the Greek πριν, with *ge;* and *gemang* is our *among.* This peculiarity gave birth to the German mode of prefixing *ge* to the perfect participle, and is the principle on which the Greek ετι, in Anglo-Saxon is corrupted into *geta, get,* or *gut.* The Anglo-Saxon *ſtellan,* the German *ſtellen,* the Swediſh *ſtalla,* the Daniſh *ſtiller,* originated in the Greek ϛελλω, which denoted firſt *to lay down the ſails of a ſhip.* Hence in the above mentioned modern tongues, it came to ſignify, *to place, compoſe,* or *adjuſt:* but the general conſequence of putting down the ſails is to give *ſtillneſs* or *tranquillity* to the ſhip. Hence ϛελλω gave birth alſo to the Anglo-Saxon *ſtillan,* and the Engliſh *to ſtill,* and to the conjunction *ſtill.* The Anglo-Saxon and Gothic uſed it conjunctively in the form of *ſtille* or *ſtylle,* and its immediate parent undoubtedly is *ſtillan,* and not *ſtellan,* as Mr. Tooke would have us believe.

Elſe, with no leſs certainty, is the Anglo-Saxon *elles,* the Latin *alias,* and the Greek αλλως, and has nothing to do with *aleſan, to diſmiſs,* and it means not *exception* or *diſmiſſion,* but a change or difference in the conſequence, or in the condition of what is expreſſed in the preceding clauſe. Thus, let the derivation be juſt, *elſe* it will not be received, *i. e. otherwiſe* it will not be received: let the derivation be juſt; if otherwiſe than juſt, it will not be received. On Mr. Tooke's principle the ſolution ſtands thus: let the derivation be juſt, *diſmiſs* it will not be received, an interpretation at once unnatural and unmeaning; and in order to give it the appearance of ſenſe and coherence, he is forced to ſuppoſe a *clauſe underſtood.* Let the derivation be juſt, diſmiſs the derivation being juſt, or diſmiſs that circumſtance, it will not be received: ſee his reſolution of ſuch examples in vol. i. p. 247. The conjunction αλλα, like αλλως, is a modification of the pronoun αλλος, *another;* and may be reſolved in the ſame way as *elſe* in Engliſh. Ουκ ηλθον καταλυσαι, αλλα πληρωσαι, I came not to deſtroy, *but* to fulfil—I came not to deſtroy, another thing, (*i. e.* I came for another thing,) I came to fulfil.

Mr. Tooke derives *but* from two different words *botan*, to *boot*, and *butan*, or *be utan*, *to be out*, or *to except*, and accordingly aſſigns the word two different ſenſes, as it is taken from the one or the other. In oppoſition to this, we maintain that *but* is the Anglo-Saxon *buton*, or *butan*, and has the ſenſe which it bears in that language of *except*, *without*, and no other but this, or one reſolvable into this. We farther maintain, that the Anglo-Saxon *buton* is the Arabic and Hebrew בת, *bata*, *to cut*, which, as it exiſts in the former with the *nunnation*, is *button*; and the principal idea implied in it is *ſeparation*. With *but* have flowed from the ſame ſource *bit*, a morſel ſeparated; *bite*, to ſeparate with the teeth. Let us apply the word thus explained. I ſaw none but two plants—two plants being ſeparated I ſaw none, or two planted being excepted or taken away, I ſaw none.

In ſuch inſtances as theſe, the negative is often omitted for the ſake of brevity; but it muſt be ſupplied before the ſentence can be explained. Again, "I have much to ſay on this ſubject, *but* I muſt proceed to another." Mr. Locke obſerved, that in ſuch inſtances, *but* intimates a ſtop of the mind, in the courſe it was going. But, ſays our grammarian, the truth is, that *but* itſelf is the fartheſt of any word in the language from intimating a ſtop. On the contrary, it intimates ſomething *more*, ſomething to follow. And, therefore, whenever any one in diſcourſing finiſhes his words with *but*, the queſtion always follows, but what? p. 205. Now, we heſitate not to ſay that Locke, though not right, is nearer the truth than Mr. H. Tooke. "I have much to ſay on this ſubject, let that however be ſeparated, or that being ſeparated or laid aſide, I proceed to another." Here then *but* denotes the *removal* of the thing which already occupied the mind, and the ſucceeding word or words mark that which is introduced to fill its place. On ſuch a removal the mind naturally looks forward to the introduction of ſomething elſe; and its expectation in this reſpect forms no part of the meaning expreſſed by *but*, but is a habit formed by experience or aſſociation. Knott having remarked, that the Catholics prayed, conferred places, and conſulted the originals; Chillingworth replies, "you pray, *but* it is not that God would bring you to the true religion, *but* that he would confirm you in your own. You confer places, *but* it is that you may confirm or colour over with plauſible diſguiſes your erroneous doctrines; not that you may judge of them and forſake them, if there be reaſon for it. You conſult the originals, *but* you regard them not, when they make againſt your doctrine or tranſlation." In all theſe places, *but* does not, as Mr. Tooke aſſerts, direct ſomething to be *added* or *ſupplied*, but denotes a ſeparation or removal of ſomething that ought not to be ſeparated or removed. You pray not that God would bring you to the true religion; you pray, motive being apart, that he ſhould confirm you in your own. You confer places, the right object is ſeparated, and you confer them that you may confirm, &c. You conſult the originals, and regard them when they make for your doctrine; this regard is ſeparated when they make againſt your doctrine or tranſlation. Thus, whatever ſenſes may be aſcribed to *but*, they are all reſolvable into one original ſignification. Nor have we need with this celebrated grammarian to trace it into two diſtinct verbs, a thing in itſelf very improbable and contrary to all analogy, nor would he have adopted ſo unlikely an hypotheſis, if it were not neceſſary for ſupporting his ſyſtem.

On the conjunction *although*, or *though*, we quote the following remark from the learned Dr. Jamieſon, in his Etym. Dictionary. "Mr. Tooke derives *though* from the Anglo-Saxon *thafian*, or *thafigan*, to allow. But there is not the ſame evidence here, as with reſpect to ſome other conjunctions illuſtrated by this acute and ingenious writer. It certainly is no inconſiderable objection to this hypotheſis, that it is not ſupported by analogy in the other northern languages. In Anglo-Saxon, *theah* ſignifies *though*, Alemannic *thach*, Icelandic *tho*. I ſhall not argue from Moes G. *thau*, in *thaujaba*, which Junius views as ſynonymous with *though*; becauſe this ſeems doubtful. In old Engliſh *thah* was written about 1264, ſee Percy's Reliques, ii. 210. which nearly approaches to the Anglo-Saxon *theah*. Inſtead of *thoch* in our oldeſt MSS. we generally find *thocht*, *althocht*. This might ſeem allied to the Icelandic *thoett*, quamvis, which, according to G. Andr. is per ſyncop. for *tho*, *at*, from *tho*, licet, etſi; Lex. p. 266. But it is more probable, that our term is merely Anglo-Saxon *thohte*. Moes G. *thahta*, cogitabat, or the participle paſt of the verb from which Engliſh *think* is derived; as in latter times *provided*, *except*, &c. have been formed. Reſolve *althocht*, and it literally ſignifies "all being thought of," or taken into account; which is the very idea given by the conjunction. The Synon. in German exhibits ſome analogy; *dachte*, being the imperfect and participle paſt of *denken doch*, although, may have been formed from the ſame verb." Though this etymology be plauſible, we do not agree with it, merely becauſe a more juſt and ſimple one may be pointed out. *Although* is *though* combined with *all*, as in the verbs *albeit*, *alone*, (for all one,) *atone*, at one. And *though* means not *thought*, but *conceſſion* or *allowance*, and is derived from the Greek obſolete δωκω, *to give*, *to grant*; and as this verb is δοω, or δωκω, (which gave birth to the firſt aoriſt εδωκα,) ſo this derived conjunction is *tho* or *though*. Its reſolution may thus be illuſtrated: "Though the book be long and tedious, I will read it with attention: be it granted, that the book be long and tedious, I will read it with attention." It is obſervable, that in its ſimple form the word is hardly capable of being explained on Dr. Jamieſon's principle. "Be it *thought* that the book is long and tedious, I will read it with attention;" whereas, on our hypotheſis, the compound form is eaſily ſuſceptible of illuſtration. Be it all granted, that the book, or grant that the book be all long and tedious, &c. It is obſervable that the word has ſpread as is ſeen above, from the ſame root into all the kindred northern tongues. So has indeed *to think*, but this comes from φθεγγω, to expreſs, which in its derived form was naturally employed to denote the operation of the mind in ſupplying the materials of diſcourſe, *i. e.* in thinking. The noun φθεγγος is alſo the parent of our word *thing*, which ſignifies any object that is the ſubject of thought. We only add that the Anglo-Saxon *thafian* is certainly of the ſame origin with *though*, the guttural *gh* being corrupted into the labial *f* in the orthography, as well as in the pronunciation.

Skinner's account of *and* is this. "Neſcio an a Lat. *addere* q. d. *add* interjecta per epentheſin *n*, ut in *render* a reddendo;" which we think a more proper etymology than that of Mr. Tooke, who derived it from *annan-ad congeriem dare*, a combination and a ſenſe of his own invention. But this word exiſts in Anglo-Saxon and Gothic, not only as a conjunction but as a prepoſition combined with words. In theſe characters it ſignifies *connection*, *union*, *reciprocation*, or *oppoſition*; and theſe ſignifications demonſtrably ſhew that its origin is the Greek αντι, ſo ſimilar to it in ſound, and preciſely the ſame with it in ſenſe. When one perſon or thing meets another to unite or co-operate, αντι, expreſſing this union, or co-operation, is the copulative *and;* but when a perſon or thing oppoſes or counteracts another, αντι, in the form of *and,* is combined with another word to expreſs *againſt* or *in return;* as *andwyrd, a word in return for a word, i. e. an anſwer; andſælis, againſt the ſun,* ſee Hicks's Anglo-Saxon Grammar, p. 87. When objects act upon the organs of ſenſe, the mind is ſuppoſed in return to act upon the impreſſions of thoſe objects in order to perceive them, and the perception ſo acquired is called in Greek αντιληψις. Hence, in Anglo-Saxon *andgit,* if we attend to the compoſition of the word, means that ſenſe which the mind *acts* or acquires by a reciprocal action on its own organs.

The conjunction, according to Mr. Harris and other grammarians, connects not *words* but *ſentences,* ſo as out of two to make one ſentence. Thus, you and I and Peter rode to London, is one ſentence made of three. But this notion Mr. Tooke refutes by the following example: two *and* two are four, A B *and* B C *and* C A form a triangle. John and Jane are a handſome pair. Does A B form a triangle, B C form a triangle? Is John a couple? Is Jane a couple? Are two four? p. 221. In truth, conjunctions as well as prepoſitions affect words and not ſentences, and their office is to combine the words ſucceeding to the words going before them, *i. e.* to combine a verb coming after with a preceding verb; a noun coming after with a preceding noun, an adjective coming after with a preceding adjective, &c.

Mr. Tooke has not given the etymon of *than,* though it exiſts only in Anglo-Saxon under the form of *thonne,* and in Gothic under that of *thana.* But in order to come at its origin, we muſt attend to the effect which external objects produce on the organs of ſenſe. When two qualities, unequal in degree, are compared, that which exceeds appears to receive by means of the contraſt an immediate augmentation; while on the other hand, the leſs ſeems to diminiſh. This being the caſe, and human nature being the ſame in all ages and countries, the ſame form of expreſſing the degrees of compariſon has obtained in all languages. Thus in Hebrew *tub min kheruſt,* good from gold, *i. e.* better than gold. The Arabs borrowed the Hebrew *min* to expreſs their comparative; and the Perſians denote it by *az,* a word of the ſame import. The Latin tongue in this inſtance is founded on the ſame general principle—*Clarior ſole,* brighter from the ſun. The French *de* and the Italian *di* are taken from the Latin *de*; and as the uſe of caſes in theſe languages has for the moſt part given way to prepoſitions, they expreſs their degrees of compariſon by theſe particles in the ſenſe of *from.* In our own tongue the mode of expreſſing the comparative ſeems alone unintelligible. But by tracing *then* to its root the myſtery vaniſhes; and we recognize the ſame great principle of nature. The imperative of the Hebrew נתן, *nattan,* which has given birth to correſponding verbs in all other languages, is תן, *than,* which is preciſely our Engliſh *than,* retaining not only its original ſound, but moreover its original ſenſe of *give, put, place.* Thus, his face was brighter *than* the ſun. *Put* the ſun (namely by the ſide) his face was brighter. Lighter *than* gold. *Put* gold, it is lighter: From the juxtapoſition of gold it becomes lighter; or as in other languages lighter *from* gold. I ſhall only add that *von, from,* of the Germans, is a corruption of the Hebrew מן, *min* or *mon, m, b, v,* being interchangeable letters. Accordingly the Germans ſay in the ſuperlative, der beſte *von* ſeinen brudern, the beſt *from* his brothers, the beſt *of* his brothers.

It ſtill remains that we notice the *adverbs* and *interjections,* but as we have already occupied ſo much of our readers attention in diſcuſſing the other parts of ſpeech, we ſhall diſpatch theſe by one or two general remarks. Adverbs, or as Mr. Harris deſcribes them, attributes of a ſecondary kind, are corruptions from nouns, adjectives, pronouns, and verbs. The name of *adverbs* given to ſuch corruptions is not, it ſhould be obſerved, deſcriptive of their nature, as diſtinct parts of ſpeech, but of their uſe in modifying the verb or adjective to which they are annexed. An adverb is often a ſubſtitute for a whole clauſe, as *here,* for *in this place; then,* for *at that time.* In this view, adverbs are the only words which properly come under the denomination of *abbreviations,* a term of which Mr. Tooke is ſo fond, and to which he ſo improperly refers ſeveral other parts of ſpeech. As to *interjections,* it may be queſtioned whether or not they can be conſidered as *articulate* ſounds, though they have been uſually honoured with a diſtinct department in language. One conſideration, however, is calculated to leave them in poſſeſſion of their hitherto enjoyed honours. Interjections, it is true, are not diſtinct names of our feelings and paſſions, and therefore they have not, like other words, derived articulation from the aſſociation of ſenſe with ſound; nevertheleſs they conſiſt of certain *expreſſions* or *cries,* which, as founded in nature, are as well calculated to recal to our minds ideas of certain emotions, as if, like other words, they had been by common conſent made the ſigns of thoſe emotions.

Grammar is alſo uſed for a book concerning the rules of grammar, which obtain in any language. See Language.

The ancient grammars are: for the Hebrew, that of rabbi Juda Chiug, which is commonly held the firſt Hebrew grammar that appeared; though it is certain, rabbi Saadias Haggaon, who lived before rabbi Juda, compoſed two works of the ſame kind: one expreſsly of grammar; and the other of the elegancies of the Hebrew tongue.

For the Greek, the oldeſt grammar is that of Gaza: the Latin ones are the works of Martianus Capella, Priſcian, and Aſconius Pedianus.

The modern grammars are; 1. For the Hebrew, that of Pagninus, the edition of Hen. Stephens, or le Preux; at Geneva, in 1592; that of Petrus Martinius at Rochel 1592; that of Buxtorf; that of Ludovicus Deus, in three languages; that of Sixtinus Amama, which is a collection from Martinius and Buxtorf; that of Bellarmine, with the notes of Muis; thoſe of F. Sglanther, of W. Schickard, and of Vict. Bythner, to the latter of which is annexed a brief account of the Chaldee, are uſeful for beginners; and thoſe of Gronovius, Schultens, Schroeder, Bayly, Bennet, Robertſon, &c.; and for the Hebrew, without the Maſſoretic points, the excellent grammar of Maſclef, to the ſecond edition of which, publiſhed at Paris in 1743, are annexed Chaldee, Syriac, and Samaritan grammars; thoſe of Sharp, Wilſon, Bates, Parkhurſt, &c. 2. For the Chaldee, the beſt are thoſe of Martinius, Buxtorf, and Lud. Deus, in three languages. 3. For the Syriac, thoſe of Amira, Myricæus, Waſerus, and Beveridge; with the Chaldee and Syriac ones of Buxtorf, of Lud. Deus in three languages, and that of Lembden. 4. For the Coptic, the Prodromus Coptus, and Lingua Ægyptiaca Reſtituta of Kircher. 5. For the Arabic, that of Erpenius, and that of Golius, which is only Erpenius's a little augmented. 6. For the Ethiopic, that of J. Ludolphus. 7. For the Perſian, that of Lud. Deus, and that of ſir William Jones. 8. For the Sancrit, thoſe of Wilkins and Carey. 9. For the Armenian, thoſe of Schroeder and Galanus. 10. For the Greek, thoſe of Mart. Rulandus Sylburgius, F. Moquet, Voſſius, Gaza, Herman, Buſby, Port Royal, Manutius, Bell, Milner, Moor, Parkhurſt, Valpy, Jones, &c. 11. For the Latin, thoſe of Diomedes, Deſpauter, the Minerva of Sanctius, thoſe of Voſſius, Ward, Clarke, and Sprat; that of Port Royal, which is only a collection from the reſt; thoſe of Lowe, of Eton, of Jones, &c. 12. For the Italian, thoſe of Berger, Lanfredini, Port Royal, and Veneroni, Baretti, &c. 13. For the Spaniſh, thoſe of Salazar, Port Royal, the abbot de Vairac, &c. 14. For the Portugueſe, that of Pereira. 15. For the French, thoſe of the abbé Regnier, and F. Buffier, &c. 16. For the High Dutch, thoſe of Claius, Hertſburgenſis, Schottelius, Boedicher, and Steinbach. 17. For the German, that of Wendeborn, &c. 18. For the Engliſh, thoſe of Wallis, Brightland, Greenwood, Lowth, Prieſtley, Murray, Crombey, &c.

GRAMMAR is alſo uſed in the ſame ſenſe with elements; as geographical grammar.

GRAMMAR, *Philoſophical*, is that which, without regarding the ſeveral idioms of particular languages, only reſpects thoſe principles that are eſſential to them all. One of this kind was propoſed by lord Bacon; not upon the analogy of words, but ſuch as ſhould diligently examine the analogy or relation between words and things. He diſapproves too curious an enquiry about the original impoſition and etymology of names. This he thinks an elegant, and, as it were, a waxen ſubject, that may be handſomely wrought and twiſted, but is attended with little truth and advantage. But, ſays he, it would be a noble kind of grammar, if any one well verſed in languages, both the learned and the vulgar, ſhould treat of their various properties, ſhewing wherein each of them excel and fall ſhort: for thus languages might be enriched by mutual commerce, and one beautiful image of ſpeech, or one grand model of language, for juſtly expreſſing the ſenſe of mankind, be formed like the Venus of Apelles, from the excellencies of ſeveral. And thus, at the ſame time, we ſhould have ſome conſiderable marks of the genius and manners of people and nations, from their reſpective languages. See Bacon's Doctrine of Delivery, § 7. and De Augm. Scient. vi. 1.

The object of philoſophical or univerſal grammar is ſpeech or language, as divided into its conſtituent parts, as a ſtatue may be divided into its ſeveral limbs; or elſe, as reſolved into its matter and form, as the ſame ſtatue may be reſolved into its marble and figure: and thus it is diſtinguiſhed from the art of logic, which conſiders ſpeech as combined or compounded; ſo that by this ſyntheſis, ſimple terms are combined to produce a truth, and two truths are combined to produce a third, &c. In this kind of grammar, the deſign is to point out the ſeveral powers and modes of expreſſion which ſounds are capable of, to trace their connections with, or relation to the ideas they repreſent; and to ſhew the actual variety of the external expreſſions of the ſame mental conceptions which different languages exhibit. By this compariſon we ſhall be enabled to judge which is the moſt adequate and convenient method of expreſſion, what is defective and what is redundant in the ſtructure of any particular language, and direct to the moſt proper method of ſupplying the defect, or leſſening the inconveniencies ariſing from the ſuperfluity. (See LANGUAGE.) See an excellent and well-known work of this kind, by the ingenious and learned Mr. Harris, called the Hermes, or a Philoſophical Enquiry concerning Univerſal Grammar, 2d ed. 1765. See alſo Tooke's Diverſions of Purley, and the preceding article GRAMMAR,

GRAMMAR, *Characters in.* See CHARACTER.

GRAMMARIAN, GRAMMATICUS, a perſon well verſed in grammar; or who teaches grammar.

The denomination grammarian is, like that of critic, frequently, though unjuſtly, uſed as a term of reproach; a mere grammarian; a dry, plodding grammarian, &c. The grammarian is conceived as a perſon wholly attentive to the minutiæ of language; induſtriouſly employed about words and phraſes; and incapable of perceiving the beauties, the delicacy, fineſſe, extent, &c. of a ſentiment.

Scaliger, however, conſidered grammarians in another light. "Utinam eſſem," ſays he, "bonus grammaticus? ſufficit enim ei, qui omnes auctores probe vult intelligere, eſſe grammaticum."

The title grammarian, it is certain, was anciently a title of honour; being given not only to ſuch as applied themſelves to grammar, or excelled in philology; but to all who were reputed learned in any art or faculty whatever, as is ſhewn by Ger. Voſſius, in his book of grammar.

The word was properly a title of literature and erudition, and was frequently given to perſons who excelled in all, or many arts, called alſo *polyhiſtores*.

Thus, Philoponus, a famous philoſopher in Juſtinian's time, remarkable for the extent and variety of his knowledge, was ſurnamed *Grammaticus*, as appears from Photius's Bibliothec.

So Saxo, the Daniſh hiſtorian, in the 13th century, got the appellation *grammaticus*: and as late as the year 1580, Thomas d'Averſa, a celebrated Neapolitan lawyer, was ſurnamed the Grammarian.

The title grammarian was anciently beſtowed on thoſe we now call *critics*, men of learning, erudition, letters, &c. and particularly ſuch as wrote well, and politely, in every kind.

It is in this ſenſe that Suetonius intitles his book which he wrote on the beſt Latin authors, "Of the celebrated Grammarians;" and that Cornelius Nepos calls the commentators on the orators and poets, grammarians; and laſtly, it is in this ſenſe the appellation is attributed by the ancients to Apion, Philoponus, and Solinus.

The moſt celebrated grammarians of the ſecond century were Aper, Pollio, Eutychius, Proculus, Athenæus, Julius Pollux, Macrobius, and Aulus Gellius: the works of theſe laſt authors are an aſſemblage of abundance of very different things, and ſubjects relating to the criticiſm of the ancient writers, and the polite literature.

If the name have loſt its ancient honour, it is through the fault of thoſe who have aſſumed it; by their treating of grammar in a low, pedantic, dogmatic manner; reducing it to words and ſyllables; and dwelling altogether on trifling puerile remarks and cenſures: whereas its ancient office was to make an accurate and thorough examen of an author; to enter into all his views; to point out the beauties, and the defects thereof; to diſtinguiſh the true beauties from the falſe; and the genuine productions of an author, from the ſuppoſititious; that is, a grammarian was then, what we call a critic now.

Thoſe who only taught to read, underſtand, and explain authors, were called grammatiſts, grammatiſtæ; in contradiſtinction from grammatici; though, in courſe of time, the grammatiſtæ have riſen in the place of grammatici, who are now preferred to that of critici.

GRAMMATICAL, ſomething relating to grammar.

We ſay, grammatical conſtruction; grammatical ſignification, &c. Idioms, as Angliciſms, Latiniſms, Greciſms, Galliciſms, &c. deviate from grammatical ſtrictneſs. Such a phraſe is not grammatically juſt; it is an idiom.

GRAMMATICAL *Criticiſm.* See CRITICISM.

GRAMME, in the new weights of France, is the weight of a centimetre of diſtilled water at its maximum of denſity, = 18.8247 French grains = 15.444 Engliſh grains = .0022063 Engliſh avoirdupoiſe pounds.

This weight is the ſtandard, or unit, of the new ſyſtem of weights; 10, 100, 1000, and 10,000 times its weight, being expreſſed by the prefixes, *deca*, *hecto*, *kilo*, and *myria*, reſpectively; and $\frac{1}{10}$th, $\frac{1}{100}$th, and $\frac{1}{1000}$dth, by the prefixes *deci*, *centi*, and *milli*. Thus, hectogramme ſignifies 100 grammes, and centigramme ſignifies the 100dth part of a gramme.

GRAMMELOUC, in *Natural Hiſtory*, the name of an Eaſt Indian ſhrub, very common in the woods and foreſts. It grows to five or ſix feet high: its leaves are very long and narrow, and terminate in a point; they are of a lively green; the fruit is carried in a bag of a triangular ſhape, of the ſize of a hazel-nut, but ſomething longer; on opening this there appear three cells, in each of which is contained one fruit, reſembling the ſeed of the palma Chriſti, but covered with a tranſparent pellicle, and a black one under that: the inſide of the fruit is white, and is of a ſharp and pungent taſte. It is a very violent medicine, operating both by ſtool and vomit, and that often, ſo as to endanger the life of the perſon who has taken it. They allay its operation by eating betel. Mem. Acad. Par. 1609.

GRAMMICA, in *Botany*, from γραμμικος, *linear*, alluding to its ſlender thread-like form, Loureir. Cochinch. 170, appears evidently by his deſcription to be a ſpecies of *Cuſcuta*, or Dodder. See CUSCUTA *chinenſis*, n. 6, which is probably the very plant.

GRAMMITIS, from γραμμα, *a line*. Swartz. Fil. 21. Claſs and order, *Cryptogamia Filices*; ſect. *Annulatæ*. Nat. Ord. *Filices*.

Eſſ. Ch. *Capſules* in ſtraight ſcattered lines. *Cover* none.

This genus differs from *Polypodium*, in having its capſules diſpoſed in ſtraight continued lines, inſtead of round dots. The *involucrum* is wanting in both. Dr. Swartz defines twelve certain ſpecies. Of theſe ſuch as have a ſimple undivided frond, like G. *lanceolata*, Swartz. t. 1. f. 4, form the moſt natural aſſemblage. The genus has, however, the advantage of admitting ſome ferns, which preceding writers did not well know how to diſpoſe of, as G. *Ceterach*, (Aſplenium Ceterach; Linn. Sp. Pl. 1538. Scolopendrium Ceterach; Sm. Fl. Brit. 1134. Engl. Bot. t. 1244.) and G. *leptophylla*, Swartz. t. 1. f. 6, which Linnæus and other botaniſts had heſitated whether to reckon a *Polypodium* or an *Aſplenium*.

Dr. Swartz mentions two doubtful ſpecies; the *Polypodium gramineum* of Lamarck, perhaps his own *Grammitis linearis*; and the *Aſplenium ſubſeſſile*, of Cavanilles lectures, n. 627, a native of the Philippine iſlands.

GRAMMONT, in *Geography*, a town of France, in the department of the Scheldt, and chief place of a canton, in the diſtrict of Audenarde, built at the foot of a mountain by the Goths, and thence called "Gotteghem." When Baldwin de Mons, count of Flanders and Hainaut, purchaſed the lordſhip of one Gerard, in 1068, he built a town, calling it after the name of the former lord, Gerardmont; and hence, by corruption, Grammont. It is partly ſituated on a hill; and the river Dender, which runs through it, divides it into the Higher and Lower Town; 20 miles W. of Bruſſels. The place contains 5948, and the canton 16,000 inhabitants, on a territory of 92½ kiliometres, in 17 communes.

GRAMMUM, a town of Hindooſtan, in Myſore; 44 miles N. of Seringapatam.

GRAMPIAN HILLS, a range of mountains, extending from E. to W. through almoſt the whole breadth of the kingdom, from Loch Lomond to Stonehaven, and deriving their name from one of them, the "Mons Grampius" of Tacitus, where Galgacus waited the approach of Agricola, and where was fought the battle ſo fatal to the brave Caledonians. This chain of hills forms the ſouthern boundary of the Highlands; though four or five counties on the N.E. of that chain have, in their eaſtern and northern parts, the name of Lowlands. The tranſition to the Grampians is gradual; the firſt chain, according to general Roy, conſiſting of the Sadley-hills on the E., the Ochills in the middle, and Campſy-hills on the W. To the Grampian chain belong Ben Lomond, 3262 feet high; Ben Ledy, 3009; Ben More, 3903; Ben Lawres, the chief ſummit, 4015; Schehallien, 3564; Ben Verlich, 3300; and other leſs conſiderable elevations on the eaſt.

GRAMPOUND, a ſmall borough and market town, in the hundred of Powder, and county of Cornwall, England, is ſituated on the banks of the river Fal or Fale, in the pariſhes of Creed and St. Probus, the eaſtern part of the borough being in the former pariſh, and the weſtern in the latter. Grampound is ſuppoſed, by Borlaſe, to ſtand on the ſcite of the Voliba of Ptolemy. Extenſive privileges were conferred on this town by king Edward I., particularly a freedom from toll throughout Cornwall: and the remains of a Caedeſula, or Felon Wood, granted with all the lands in it by this monarch, are ſtill extant. The right of holding a market was a grant from John of Eltham, earl of Cornwall, and brother to Edward III., who, after the death of earl John, confirmed the firſt charter, and made the town a borough: but no repreſentatives were returned to parliament till the reign of Edward VI. Two members are now elected by the magiſtrates and inhabitants paying ſcot and lot; but the whole number of voters is only 25. The corporation conſiſts of a mayor, eight magiſtrates, a recorder, and a town-clerk. The church is about half a mile from the town, in the pariſh of Creed; but a ſmall chapel of eaſe ſtands near the centre of the borough. Grampound is 263 miles S.W. from London; has three annual fairs, and a weekly market on Saturdays. In the return under the late act, the inhabitants amounted to 525, the houſes to 80. Polwhele's Hiſtory, &c. of Cornwall. Beauties of England and Wales, vol. ii.

GRAMPUS, in *Ichthyology*, the DELPHINUS *orca* of Linnæus; which ſee.

GRAMZOW, in *Geography*, a town of Brandenburg, in the Ucker Mark; 8 miles S.E. of Prenzlow.

GRAN, or ESZTERGON, or *Strigonia*, a town of Hungary, ſituated near the conflux of the rivers Gran and Danube; the ſee of an archbiſhop; 55 miles S.E. of Preſburg. N. lat. 47 44′. E. long. 18°.

GRAN, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 62 1′. E. long. 17° 22′.

GRANA, a ſea-port of Spain, in Galicia; 2 miles W. of Ferrol. N. lat. 43° 29′. W. long. 8° 15′.

GRANA *Figlia*, in the *Materia Medica*, the fruit of a ſpecies of ricinus.

GRANA *Paradiſi*, or *Greater Cardamoms*, are the ſeeds of the amomum of Linnæus.

GRANA *Regia*, the ſeeds of the common ricinus, called by ſome palma Chriſti.

GRANADA, or GRENADA, ſometimes called *Upper Andaluſia*, in *Geography*, a kingdom or province of Spain, occupying half of the eaſtern extremity, and all the ſouthern part of Andaluſia as far as the ſtraits of Gibraltar, has the form of a pyramid with its baſe to the eaſt, on the kingdom of Murcia, and its apex to the ſouth-weſt towards the Straits. Its length is 58 leagues from the E. to the S.E; the breadth at its apex ſeven from the S.W. to the N.E., and at its baſe 28 from S. to N.. To the E. and N.E., it is bounded by the kingdom of Murcia; to the S. and S.E. by the Mediterranean; to the W., by the kingdom of Seville; to the W. and N.W. by that of Cordova;

and to the N.W. and N., by that of Jaen. It lies between 36° 20′ and 38° N. lat. and between 5° 5′ and 1° 30′ W. long.; and contains about 661,600 inhabitants. This province has three ſea-ports on the Mediterranean; *viz.* that of Amunécar, defended by three forts of little importance; that of Almeria, which was celebrated under the Arabs; and that of Malaga, now the moſt flouriſhing and moſt frequented. Its principal towns are Granada, the capital, Malaga, Almeria, Guadix, Motril, Marbella, Velez-Malaga, Baza, Vera, Ronda, Loja, Santa-Fé, Hueſca, Antequera, and Alhama. Its rivers are the Verde, Xenil, Las Feguas, Guadalentia, Guadavar, Guadalmeja, Rio de Almeria, Rio Frio, Guadalmerina, Darro, Andaraye, Guadix, Bravata, Marehan, Almancara, Aguas, Culebras, and Guadalete. This province is very mountainous; its chief mountains being the following, *viz.* the Sierra Vermella or Vermeja, *i. e.* red mountain, ſo called from the colour of the ſoil, the Sierra de Filabre, the Sierra de Bujo, the Sierra Blanquilla, or white mountain, denominated from its appearance at a diſtance, and the Sierra de Javal-Cohol. The Sierra Nevada is a grand and beautiful mountain ſituated nearly in the centre of the province: it takes its name from the ſnow that remains on it through the year. It is very lofty, can be ſeen at a very great diſtance, and is well known to mariners, who diſcover it far out at ſea. The Sierra Alpuxara, likewiſe in this province, is formed by the contiguity of ſeveral lofty mountains, and generally called the Alpuxaras. Theſe afforded a retreat to a conſiderable number of Moors driven from Granada, who remained there 120 years, till their total expulſion from Spain. The Sierra de Ronda lies on the ſouthern and eaſtern part of the province of Granada; ſtretching N. and E. in that of Seville, and running S. towards the ſtraits of Gibraltar. Granada, although mountainous, contains plains of conſiderable extent, and pleaſant valleys abounding in ſprings.

Granada, as a part of Andaluſia, was firſt known to the Phœnicians and then to the Carthaginians, who were expelled by the Romans; and they alſo were expelled, in the fifth century of the Chriſtian era, by the Vandals; and the Goths, led by Euric, afterwards took poſſeſſion of the country. The Arabs entered Spain by Andaluſia in the year 711; and after the battle of Xeres, which decided its fate, as well as that of Spain, it belonged to the caliphs of Damaſcus, and then to thoſe of Bagdad; till at length Abdal-rahman, or Abderame, a prince of the blood-royal of the Ommiades or Almohades, ſeized on the throne of Spain in 755. In the year 1027 the empire of the Moors in Spain was diſmembered; and in 1221 the kingdom of Granada was diſſolved. Soon after this period, *viz.* in 1236, Mahomed Alamir, or Alhamar, founded anew the kingdom of Granada; and his deſcendants preſerved for about 2½ centuries the throne, which he tranſmitted to them. It was reſerved for Ferdinand V. and Iſabella his queen, to give the laſt blow to the power of the Moors, by depriving them of the kingdom of Granada at the end of the 15th century. The capture of Malaga, Aug. 18th 1487, facilitated the ſiege of Granada, the capital of the province, into which the Moors had collected their whole force. They were attacked in 1491, and after a ſiege of upwards of a year, the town was obliged to ſurrender to the Catholic armies; and thus in 1492 the Mooriſh empire in Spain terminated. The extent of Granada at this time was 70 leagues long and 30 broad; it contained, as it is ſaid, 32 great towns, 97 ſmaller ones, upwards of 2000 boroughs and villages, and 3,000,000 of inhabitants. The revenue derived from it amounted annually to 700,000 ducats; and gold and ſilver abounded more in this kingdom than in any other country of Europe. But the aſtoniſhing fertility and wealth of this country paſſed away with its old inhabitants, and were ſucceeded by a deplorable degree of indolence, poverty, and miſery.

Granada, or *Grenada*, the capital of the province above deſcribed, and an archbiſhop's ſee, is a large city, which was entirely built by the Moors in the tenth century; and in 1235, after having previouſly belonged to the dominions of the kings of Cordova, it became the capital of a new empire, and ſoon acquired great celebrity in the Mooriſh annals. This town, which in a ſhort time became important for its extent, population, wealth, and power, and the magnificence of its buildings, became, in proceſs of time, the ultimate reſource and laſt bulwark of the authority of the Moors in Spain. We have already given an account of its ſurrender to the Catholic kings. At that period it was three leagues in circumference, its ramparts were defended by 1030 towers; its walls incloſed 70,000 houſes, and a population of 400,000 inhabitants. It had an army of 60,000 men; and the number that defended its ramparts in 1491 and 1492 amounted to 100,000. It was protected by two fortreſſes, each of which was large enough to contain 40,000 men.

This town ſtands on two hills, at the end of the plain called Vega de Granada, near the Sierra Nevada, on the banks of the Darro which runs through it, and of the Xenil which bathes its walls. The two fortreſſes juſt mentioned are on the ſummits of the hills on either ſide, thus commanding the town, which itſelf commands the beautiful adjacent country ten leagues round; and its ſituation is delightful. The plain, at the extremity of which it ſtands, is ſomewhat ſloping; its diameter is from nine to ten leagues, and its circumference 30: on the N. it is bounded by the Sierra Nevada and the mountains of Elvira, and on the other ſides by ſucceſſive and varied amphitheatres of hills agreeably planted with vines, olives, mulberry, lemon, and orange trees, &c.; it is watered by five rivers, interſected by various canals, ſupplied from limpid rivulets with a number of ſprings; and it is covered with meadows, foreſts of oak, woods of orange-trees, orchards, ſugar-canes, corn, flax, and in ſhort all kinds of fruits and vegetables.

Granada was formerly divided into four quarters, *viz.* Granada, Alhambra, Albayzin, and Antiquerula. Of theſe, the firſt, or Granada, is the handſomeſt, moſt important, moſt agreeable, beſt built, and beſt inhabited part of the town. It occupies the commencement of the plain, and a part of the vallies between the two mountains; it is embelliſhed with a number of fountains, large gardens, handſome ſquares, and fine buildings: it is inhabited by the nobility, clergy, magiſtracy, and the richeſt of the citizens; and the principal markets are ſituated in it. The quarter of Alhambra, properly ſpeaking, is only a great fortreſs, ſituated on a mountain, called Sierra del Sol, or mountain of the ſun; it was the reſidence of the kings, whoſe palace ſtill poſſeſſes great beauties. (See the deſcription of it under ALHAMBRA.) The quarter of Albayzin reſembles a fauxbourg raiſed on a hill, where was formerly a fort, which commanded and protected the town, from which it is ſeparated by a rampart. It contains about 400 houſes. Antiquerula has the appearance of another fauxbourg built upon the plain; it was peopled by ſettlers from Antequera, and is at preſent chiefly inhabited by dyers and ſilk weavers. Among the numerous ſquares of Granada we may ſpecify as the handſomeſt, El Campo, in which is a hoſpital; the Plaza Mayor, which is ſpacious, and uſed for public ſhows, particularly the bull-feaſts; and the Bivarambla, embelliſhed by a beautiful jaſper fountain, and by the two fine edifices of the Alcaxeria, which was uſed by the

Moors as a bazar, and ſtill appropriated to the purpoſe of a market-place, and containing about 200 ſhops; and the palace of the chancery. To theſe two buildings we may add an ancient moſque, now a pariſh-church, the cathedral, two hoſpitals, and the two palaces of the Alhambra. The cathedral is not large, but has a handſome dome, reſting on twelve arches, ſupported by as many large pilaſters; the vault is full of paintings and richly gilt, and two rows of gilded balconies run round it over the arcades. Statues of the twelve apoſtles in bronze, gilt, and as large as life, are placed againſt the twelve columns. The vault of the church of the Chartreux is covered with fine paintings in freſco, by Antonio Palomino. In many of the houſes are found remains of baths, conſtructed by the Moors; and moſt of the houſes are embelliſhed with fountains, which ſupply water not only for domeſtic purpoſes, but for moderating by its coolneſs the heat of a climate extremely warm in ſummer.

Granada is an archbiſhopric, worth 25,000*l.* a year, containing a cathedral chapter, ſix collegiate chapters, and 194 pariſh churches. This city is the ſeat of a royal chancery, divided into ſix chambers, and compoſed of a preſident, twenty-five counſellors, two ſolicitors, and one alguazil mayor. The intendant of the province reſides here; and the town has a criminal judge, two alcades mayors for the adminiſtration of juſtice, a municipality compoſed of a certain number of regidors, a war auditor, and a tribunal of the inquiſition. The Alhambra has a juriſdiction peculiar to itſelf. The city is divided into twenty-three pariſhes, with forty convents, three beatarios, ſeventeen hermitas or chapels, nine hoſpitals, and eight colleges. Granada has an univerſity, founded A. D. 1531; and an academy for painting, ſculpture, and architecture, conducted at the king's expence, and free for all. The extent of Granada is nearly the ſame as it was under the Moors; but its population is very much diminiſhed. In 1614, at the period of the total expulſion of the Moors from Spain, a very conſiderable number of the families of that people left it. The town, which had counted 400,000 individuals within its walls, and which had armed 100,000 warriors in its defence, is now reduced, according to the government returns ſtated by Mr. Townſend, (Travels in Spain, vol. iii.) to 52,325 ſouls; although, upon good authority, he ſays, they may be reckoned 80,000. Under the Moors, Granada carried on a great trade, and was famous for its own productions; it manufactured cloths, various kinds of woollen ſtuffs, and a great quantity of ſilks. Indeed, it is not poſſible to think of manufactures in Granada, without calling to mind the expulſion of the Moors, and pauſing to examine the policy of that ſtrong meaſure. They were numerous, and, in conſequence of their induſtry, accompanied with frugality, they had acquired opulence and power. It is ſaid, (ſee Townſend, ubi ſupra,) that of 100,000, condemned by the inquiſition for apoſtatizing from the Chriſtian faith, 4000 had been burnt without any good effect. Philip III., in the year 1609, baniſhed to Africa 140,000 out of the kingdom of Valencia; and in the three years following, 600,000 from Seville, Murcia, and Granada. If to theſe we add the multitudes that periſhed by famine, and by the ſword, we ſhall be inclined to ſtate the loſs to Spain at one million of its moſt active ſubjects. This loſs, added to what the country had ſuſtained by the previous expulſion of 800,000 Jews, with all their wealth, in the reign of Ferdinand and Iſabella, was, under ſuch a government as that of Spain, irreparable. The Moors are acknowledged by the beſt Spaniſh writers to have excelled in agriculture, particularly in watering their lands, in the cultivation of mulberry trees, the ſugar-cane, rice and cotton, all introduced by them; in their peculiar breed of horſes; and in the manufactures of ſilk, of paper, and of gun-powder, firſt brought into Europe by them. The manufactures of Granada, however, continued to be ſomewhat flouriſhing about the middle of the ſixteenth century. Some regulations, favourable to them, were adopted and eſtabliſhed in 1552. At that time great attention was paid to the production of ſilk in Andaluſia, and the trade in it was proſperous. But, in proceſs of time, as the conſequence of the expulſion of the Moors, the privileges and immunities granted to the hidalgos or knights, bearing in the kingdom of Granada the proportion of 1979 to 652,990, the whole number of inhabitants, and various oppreſſive reſtrictions and burthens, agriculture languiſhed, ſilk was neglected, the manufactures decayed, and in the ſeventeenth century few or none remained. Some attempts have been lately made to revive them; ſome new ones have been eſtabliſhed, in which ribbons and ſilk ſtuffs are made; but they have not been very proſperous. Here is a manufacture of gunpowder on the king's account. In the production of nitre, at the ſalt-works near this town, about 100 men are employed in ſummer, and 26 in winter; and from theſe government obtains 3000 quintals annually. In the vicinity of Granada are ſome conſiderable plantations of the ſugar-cane.

The environs of Granada are delightful; the public walks, of which the moſt frequented are thoſe on the banks of the Xenil with cooling ſhade and refreſhing fountains, and another, more wild and romantic, by the ſide of the Darro, are pleaſant; and the country all round the city appears to be well cultivated. The market gardens appear like a wilderneſs of fruit trees, and yet are covered with the moſt luxuriant crops of all kinds of vegetables. Every cottage has a little court, or bower, formed by a lattice frame, and wholly ſhaded by the vine; under which, in the evening, the peaſant aſſembles his family to take refreſhment; whilſt the nightingale from every tree is uttering his plaintive note. Theſe gardens are all plentifully watered. Granada abounds in marbles, remarkable for their variety, and fineneſs of grain and beauty; and it has alſo a variety of alabaſters, jaſpers, and other precious ſtones. Its mineral waters are alſo various and abundant.

GRANADA, a ſmall town in the province of Nicaragua, ſeated at the S.E. extremity of the lake of Nicaragua. It has conſiderable commerce in indigo, cochineal, hides, and ſugar. In the year 1680, this town, and alſo Leon, the capital of the province, were pillaged by the buccaneers of America. N. lat. 11° 15'. W. long. 86° 15'.

GRANADA, *New*, a viceroyalty of the dominions of Spain, in South America, extending from the river Tumbez to the Caribbean ſea; that is, from S. lat. 3° 30', to N. lat. 12°, or about 930 geographical miles; its medial breadth may be ſtated at 4° or 240 geographical miles. This grand and opulent viceroyalty, though it dates its origin from the year 1718, was, after a long ſuppreſſion, only eſtabliſhed finally in 1740. It is ſometimes called from its capital Santa Fé, and compriſes the following provinces: *viz.* Jaen de Bracamoros, Loja, Cuença, Macas, Riobamba, Guayaquil, Quito, Tacames, Paſtos, Barbacoas, Popayan, Rapuſo, Novita, Antioquia, Santa Fé, San Juan de los Llanos, Merida, Santa Marta, Carthagena, Zinu, Choco, and the Tierra Firmé, including the three diſtricts of Darien, Panama or Tierra Firmé proper, and Veragua. The ample provinces which form this viceroyalty were moſtly diſcovered and annexed to the dominions of Spain about the year 1536, by Sebaſtian de Benalcazar, and Gonzalo Ximenes de Queſada, two of the braveſt officers employed in the conqueſt of America. The former, who commanded at Quito, made an attack from the ſouth, and the latter from Santa Marta on the north. As the original inhabitants of this region were farther advanced in improvement than any people of America, but the Mexicans and Peruvians, they defended themſelves with great reſolution and good conduct. The abilities and perſeverance of theſe two officers ultimately prevailed, after encountering many dangers, and reduced the country into the form of a Spaniſh province. The kingdom of New Granada was at firſt governed by the royal audience founded in 1547, and by its preſident the captain-general. In 1718 this arrangement was changed, and the viceroyalty was eſtabliſhed ; but it was ſuppreſſed in 1724, and finally eſtabliſhed in 1740. When the conquerors firſt took poſſeſſion of this country, it was more populous than the generality of the other ſtates ; and its want of population at this time prevents its being rendered one of the richeſt in America. The government reſembles that of the other viceroyalties ; with a royal audience at Santa Fé, the capital, a tribunal of accounts, a treaſury, and a royal mint. The royal audience ſits in the ſame hall for civil and criminal cauſes ; there being five judges, a fiſcal, a protector of the Indians, amd other officers. The governments, comprehended in the royal audience, are Carthagena, Panama, Santa Marta, Maracaibo, and Porto Bello, with the diſtrict of the river Hacha ; in the interior are Antioquia, Choco, Veragua, Mariquita, Giron, Neiva, and the Llanos. There is alſo a royal audience at Quito, and a governor and preſident, who rules the ſouthern provinces in ſubordination to the viceroy of New Granada. But Quito remains a biſhopric while Santa Fé is an archbiſhopric, founded in 1562, with Popayan and Carthagena as ſuffragans. In 1783 the archbiſhop was named viceroy. There are alſo ſeveral miſſions in the country called Los Llanos, and on the Apari, Meta, and Caſanari, with ſome little villages or ſtations. Thoſe on the Upper and Lower Orinoco, and river Negro, aſſigned to the Capuchins in 1769, belong to the government of Caraccas.

The population of this viceroyalty has not been accurately aſcertained ; but if the general population of Caraccas amounts to 728,000, it is probable, ſays Mr. Pinkerton, that rather more than one million may be allowed for that of Granada. Of the amount of its revenues we have no certain documents ; but from the amount of the annual coinage at Santa Fé and Popayan, and allowing a tenth to the king for the expences of government, they cannot be leſs than 220,000 pounds. The ſtate of the military force is inconſiderable ; nor would it be eaſy in theſe diſtant provinces to collect an effective force of five or ſix thouſand men. The capital of this viceroyalty is BOGOTA, or *Santa Fé de Bogota*, for an account of which ſee thoſe articles. Of the other principal cities and towns notice is taken in the progreſs of this work. The commerce of this viceroyalty has very much ſuffered by the ſuppreſſion of the galeons ; and though it has been encouraged by the freedom granted in 1778, it is not yet recovered. The contraband trade, carried on by the Engliſh on the Muſquito ſhore, and from the Portugueſe ſettlements in Brazil, and the Caribbean ſea, has impeded the exertions of the Spaniſh coloniſts. Its commerce is allowed to be very diſproportioned to the diſtinguiſhing advantages of this territory. Its exiſtence almoſt depends on the gold from the mines, a few manufactures, and ſome native products. The manufactures are carried on chiefly at Tunja, Socorro, Velez, and other towns and villages towards the plains ; and they conſiſt of cotton cloths, carpets, counterpanes, and woollens of various deſcriptions, that ſupport internal trade. The northern provinces produce excellent wood for the conſtruction of ſhips ; and the dyeing woods are ſuperior to thoſe of Campechy. The mahogany of Panama is exquiſitely beautiful, and ſuperior to all others. The chocolate from the banks of the Magdalena is eſteemed equal to that of Caraccas ; and vaſt harveſts of cotton and tobacco might be gathered, while the navigable rivers Magdalena and Atrato, and the ports of Carthagena and Santa Marta, offer eaſy and commodious outlets to the European markets. Its intermediate mart of Havanna preſents another convenience to the traffic of this viceroyalty. The culture of coffee and chocolate is in a proſperous ſtate in the province of Guayaquil. The ſalutary and uſeful vegetable productions of theſe extenſive provinces are ſo numerous and diverſified, that induſtry alone is wanting to open all the ſources of commerce.

The climate of this extenſive viceroyalty preſents great variety ; for though it lies under the equator, and in its vicinity, the enormous and ſublime chain of the Andes, running N. and S. from the Table land of Quito and Cuença to the Caribbean ſea, and environs of Santa Marta, occaſion every diverſity from the ſnow and ice of the poles to the rain and heat of the tropics. The great rivers Magdalena and Cauca riſe and terminate in this province. The animals are in general ſuch as are common to the whole continent of S. America ; and the inhabitants breed a number of horſes and mules which they ſend to Peru. The mineralogy of New Granada cannot be reckoned unimportant ; Alcedo, cited by Pinkerton, obſerves, that gold is here more abundant than in any other part of America. The richeſt provinces in this reſpect are thoſe of Choco and Antioquia ; and they are eaſily acceſſible by the rivers Atrato and Guacuba, which enter the gulf of Darien, and are navigable for a conſiderable extent. Silver is alſo remarkably pure ; and the mines of Marquetones, in the diſtrict of Pamplona are ſo rich, that if they had a ſufficient number of labourers, they might rival thoſe of Potoſi, as they ſometimes yield eight marks of ſilver in the hundred weight. Copper and lead alſo abound, but they are not much valued ; and the various kinds of precious ſtones are plentiful. Platina has been thought to be the peculiar product of Choco. Salt is obtained in great abundance. The natives uſe maize, or the Caſſava root, inſtead of bread. Game is abundant ; and the rivers and lakes furniſh an ample ſupply of fiſh. The natives are tall ; and wear thick, white, or variegated cloaks, which they tie round the waiſt with a ſaſh. They adorn their heads with ſtrings of painted flowers very ingeniouſly made of cotton. Robertſon's America, vol. iii. Pinkerton's Geog. vol. iii.

GRANADIER, GRENADIER, or *Granadeer*, a foot-ſoldier, who is armed with a firelock, bayonet, and in ſome ſervices a hanger, and a cartridge-box that will hold 36 rounds. They wear a high cap, fronted with a piece of braſs, on which the king's arms is generally repreſented, &c. and a piece of cloth upon their ſhoulders, called a wing. In ſome armies they have better pay than a common ſoldier. They were firſt eſtabliſhed in France in 1667, and ſoon after formed into companies : they were firſt known in England in 1685.

GRANADIERS, or *Grenadiers, Horſe*, called by the French *grenadiers volans*, or flying granadiers, are ſuch as are mounted on horſeback, but fight on foot and on horſeback. Theſe were firſt eſtabliſhed in France by Lewis XIV. in 1676, and formed into ſquadrons.

Every battalion of foot has generally a company of granadiers belonging to it ; which generally take the right of the battalion ; and, being the talleſt and ſtouteſt men, frequently are the firſt in attacks.

We have had in England two troops of horſe granadier guards; the firſt raiſed in the year 1693, and the ſecond in 1701.

GRANADILLA, in *Botany*, the diminutive of the Spaniſh name of the Pomgranate, *Granada*, uſed in the Weſt Indies, and retained by Tournefort and Adanſon, for the *Paſſiflora* of Linnæus. This appellation is particularly applied to the fruit of *Paſſiflora quadrangularis*, much eſteemed by Weſt Indians, and ſometimes ripened in England.

GRANADO, GRANADA, or *Grenade*, in the *Military Art*, a hollow ball or ſhell, of iron, braſs, or even glaſs, or potter's earth, filled with gun-powder, and fitted with a fuzee to give it fire.

The name granado takes its riſe hence, that it is filled with grains of powder, as a pomegranate is with kernels.

Of theſe there are two kinds; the one large, the other ſmall: the firſt are to be thrown at the enemy by a mortar, properly called *bombs*, or *ſhells*. The latter to be caſt with the hand, and thence denominated *hand-granados*.

The beſt way, Caſimir obſerves, to ſecure a man's ſelf from the effect of a granado, is, to lie flat down on the ground, before it burſt.

The common, or hand granado, is a little, hollow ball of iron, tin, wood, paſteboard, or other matter, filled with ſtrong powder, lighted with a fuzee, and thus thrown by hand into places where men ſtand thick; and particularly into trenches and lodgments. Theſe are now ſunk into diſuſe.

Their compoſition is the ſame with that of *bombs*; which ſee. For ſize, they are uſually between two and three inches in diameter, about the bigneſs of a common iron bullet, and weigh about three pounds; as to dimenſions, they are commonly in thickneſs one-eighth, one-ninth, or one-tenth of their diameter; their aperture, or orifice, about $\frac{1}{10}$ wide, as preſcribed by Caſimir.

Thuanus obſerves, that the firſt time granados were uſed, was at the ſiege of Wachtendonch, a town near Gueldres; and that the inventor was an inhabitant of Venlo; who, in making an experiment of the effect thereof, occaſioned two-thirds of that city to be burnt; the fire being kindled by the fall of a granado.

Bombs were known long before the invention of granados. The ancients had a ſort of ollæ, or fire-pots, ſomewhat of the ſame nature with our granados, but they were much leſs perfect.

Caſimir mentions a ſort of blind granados, without any aperture, or fuzee, as not needing to be lighted; but being thrown with a mortar, they take fire of themſelves whenever they fall on any hard ſolid object.

GRANARD, in *Geography*, a neat, new built market and poſt town of Ireland, in the county of Longford. Adjoining is a remarkable hill or mount called the *Moat of Granard*, thought to be artificial, and the ſeite of a Daniſh fort, which commands from its ſummit a moſt extenſive proſpect into ſix or ſeven adjoining counties. It is 52 miles from Dublin, and 12 from Longford.

GRANARY, in *Agriculture*, a building contrived for laying up and ſtoring corn, in order to preſerve it for a length of time. They have, near Grand Cairo, magazines or granaries, called "Joſeph's granaries," defended with wooden walls, in which vaſt quantities of grain are annually preſerved; and many parts of Africa abound with granaries of this kind. They are frequently deep pits made in the ſolid rock; the deſcent into them being juſt large enough for a man to go down; but they grow larger as ſoon as the perſon is in, and are uſually ſquare, from thirty to forty feet in diameter. In theſe the great men of the country preſerve their corn; they firſt cover over the floor with ſtraw, then they lay on the corn, ſtill, as the heap riſes, placing a thin bed of ſtraw between the corn and the ſides, as they did at the bottom. In this manner they proceed till the whole cavity is filled: when this is done they cover the mouth or entrance with a ſort of hurdle of green boughs of trees, interwoven one with another. This they cover with about two feet thickneſs of ſand, and over this raiſe a ridge of earth, well beaten together, in order to throw off the rain both ways, that none may ſettle on the place and ſoak into the magazine. The corn thus ſtored up keeps three, four, or more years very good; and, not unfrequently, the proprietor being taken off by the ſeverity of the eaſtern governments, under which they live, the magazine is forgotten, and ſome accident diſcovering it many years afterwards, the corn is almoſt always found perfectly good in it. All the care they take, in regard to the grain, is to expoſe it two or three days to the ſun's heat, to dry it thoroughly, before they carry it into the magazine.

It may be ſtated further, that in the duchy of Lithuania, and in the Ukraine, the people alſo preſerve their corn in the ſame manner, in wells or pits made in dry places: but in theſe countries great care is to be taken in the opening of theſe ſtore-rooms; for, if people deſcend into them before they have had ſufficient communication with the freſh air, they are often killed by the damps; this, however, is eaſily guarded againſt. By theſe, and numerous other inſtances of the practice of other countries, it appears evident that ſubterranean granaries may occaſionally be highly uſeful for the purpoſe of preſerving grain in particular ſituations and circumſtances.

But the common granaries may, with proper care, be rendered much more uſeful than they are at preſent. The grand caution neceſſary to this purpoſe is, to guard againſt the too great humidity, which is often the caſe in places where there is a great number of doors and windows. A too free acceſs of the external air is alſo to be guarded againſt; as this has not only a tendency to produce the above effect, but is liable to bring in with it the ova or eggs of a number of different inſects, which prey upon and deſtroy the corn. A third caution is, when the corn is the produce of the country where it is preſerved, not to fill the place with the crop of one place only, but to mix the harveſts of two as different provinces as may be, the one dry, the other moiſt, or otherwiſe differing as much as may be; thus the contrary qualities of the one may prevent the deſtruction of the other. Theſe are the principal rules to prevent the corrupting of corn: but when the miſchief is once begun, it will be very difficult to ſtop it; all the care that can be employed ſhould, of courſe, be taken in regard to theſe as ſpeedily as poſſible.

It may be obſerved, that the chief points to be attended to in the erecting of granaries, are to make them ſufficiently ſtrong, and to give them ſuch a ſituation as may expoſe them to the moſt drying winds. But in conſtructing a granary merely for the accommodation of a farm, it is unneceſſary, Mr. Bateſon obſerves, in the ſecond volume of Communications to the Board of Agriculture, to attend to all thoſe circumſtances reſpecting ſtrength, ſituation, &c. which ought to be obſerved in building an extenſive granary, where large quantities of grain are ſometimes depoſited. A farmer ſeldom wiſhes to have a great deal of his thraſhed corn on his hands at once; nevertheleſs there ought, on every farm, to be a place of ſecurity, capable of containing, at leaſt, one-third or one-half the grain produced annually on the farm. Where the practice of houſing corn is followed, there is little or no room, he remarks, within the barn for a granary; but where this is not the practice, particularly where there is a thraſhing mill, the granary may be eaſily made over the barn; which, with proper tackle for hoiſting the ſacks from below, is, he thinks, the moſt convenient and leaſt expenſive place a farmer can have it in.

The ordering of the corn in many parts of England, after being ſeparated from the chaff, duſt, and other impurities, and well ſcreened, is this: after bringing it into the granaries, it is ſpread about half a foot thick, and turned from time to time, about twice in a week; once a week they alſo repeat the ſcreening. This ſort of management is continued two months, and after that it is laid a foot thick for two months more, and during this time turned once a week, or twice, if the ſeaſon be damp, and now and then again ſcreened over. After about five or ſix months, it is raiſed to five or ſix feet thickneſs in the heaps, and then turned once or twice in a month, and ſcreened now and then. When it has lain two years, or more, it is only turned once in two months, and ſcreened once a quarter; but how long ſoever it is kept, the oftener the turning and ſcreening are repeated, the better the grain will be found to keep. It is proper to leave an area of a yard wide on every ſide the heap of corn, and other empty ſpaces, into which it may be turned and toſſed as often as there may be occaſion. In Kent they make two ſquare holes at each end of the floor, and one round in the middle, by means of which they throw the corn out of the upper into the lower rooms, and ſo up again, to turn and air it the better. Their ſcreens are made with two partitions, to ſeparate the duſt from the corn, which falls into a bag; and when ſufficiently full, this being removed, the pure and good corn remains behind.

By theſe means corn has been kept in granaries thirty years; and it is aſſerted, that the longer it is kept the more flour it yields, in proportion to the corn, and the purer and whiter the bread is, the ſuperfluous humidity only having been evaporated in the keeping. At Zurich, in Swiſſerland, it is ſaid that corn has been kept eighty years, or longer, by the ſame methods of management.

It is ſtated that the public granaries at Dantzick are ſeven, eight, or nine ſtories high, having a funnel in the midſt of every floor, to let down the corn from one to another. They are built ſo ſecurely, that, though every way ſurrounded with water, the corn contracts no damp, and the veſſels have the convenience of coming up to the walls for their lading. The Ruſſians preſerve their corn in ſubterranean granaries, of the figure of a ſugar-loaf, wide below and narrow at top: the ſides are well plaſtered, and the top covered with ſtones. They are very careful to have the corn well dried before it is laid into theſe ſtorehouſes, and often dry it by means of ovens, their ſummer dry weather being too ſhort to effect it ſufficiently for the purpoſe.

Different contrivances have been propoſed by M. Du Hamel and Dr. Hales, for ventilating or blowing freſh air through corn laid up in granaries or ſhips, in order to preſerve it ſweet and dry, and to prevent its being devoured by weevils or other inſects. This may be done by nailing wooden bars or laths on the floors of the granary, about an inch diſtant from each other, when they are covered with hair-cloth only; or at the diſtance of two or three inches, when coarſe wire-work, or baſket-work of oſier, is laid under the hair-cloth, or when an iron plate full of holes is laid upon them. Theſe laths may be laid acroſs other laths, nailed at the diſtance of fifteen inches, and two or more deep, that there may be a free paſſage for the air under them. The under laths muſt come about ſix inches ſhort of the wall of the granary at one end of them, on which end a board is to be ſet edgeways, and ſloping againſt the wall: by this diſpoſition a large air-pipe is formed, which, having an open communication with all the interſtices between and under the bars, will admit the paſſage of air below forcibly through a hole at the extremity of it, into all the corn of the granary, that will conſequently carry off the moiſt exhalations of the corn. The ventilators for ſupplying freſh air may be fixed againſt the wall, on the inſide or outſide of the granary, or under the floor, or in the cieling; but wherever they are fixed, the handle of the lever that works them muſt be out of the granary, otherwiſe the perſon who works them will be in danger of ſuffocation when the corn is fumed with brimſtone, as is ſometimes done for deſtroying weevils. Small moveable ventilators will anſwer the purpoſe for ventilating corn in large bins or in ſmall granaries, and may be eaſily moved from one bin to another. If the granary or corn-ſhip be very long, the main air-pipe may paſs lengthwiſe along the middle of it, and convey air, on both ſides, under the corn. In large granaries, large double ventilators, laid on each other, may be fixed at the middle and near the top of the granary, that they may be worked by a wind-mill fixed on the roof of the building, or by a water-mill. The air is to be conveyed from the ventilators through a large trunk or trunks, reaching down through the ſeveral floors to the bottom of the granary, with branching trunks on each floor, by means of which the air may be made to paſs into a large trunk along the adjoining croſs walls: from theſe trunks ſeveral leſſer trunks, about four inches wide, are to branch off, at the diſtance of three or four feet from each other, which are to reach through the whole length of the granary, and their farther ends to be cloſed: ſeams of one-tenth or one-twelfth of an inch are however to be left open at the four joinings of the boards, where they are nailed together, that the air may paſs through them into the corn. In ſome of theſe leſſer trunks there may be ſliding ſhutters, in order to ſtop the paſſage of the air through thoſe trunks which are not covered with corn; or to ventilate one part of the granary more briſkly than others, as there may be occaſion. There muſt alſo be wooden ſhutters, hung on hinges, at their upper part, ſo as to ſhut cloſe of themſelves; theſe muſt be fixed to the openings in the walls of the granary on their outſide: by theſe means they will readily open to give a free paſſage for the ventilating air, which aſcends through the corn, to paſs off, but will inſtantly ſhut when the ventilation ceaſes, and thereby prevent any dampneſs of the external air from entering: to prevent this more fully, the ventilation ſhould be made only in the middle of dry days, unleſs the corn, when firſt put in, is cold and damp.

But in ſmaller granaries, where the ventilators muſt be worked by hand, if theſe granaries ſtand on ſtaddles, ſo as to have their lower floor at ſome diſtance from the ground, the ventilators may be fixed under the lower floor, between the ſtaddles, ſo as to be worked by men ſtanding on the ground without or within the granary. A very commodious and cheap ventilator may be had for ſmall granaries, by making the door of the granary ſerve the purpoſe, which may be eaſily done by making a circular ſcreen, of the ſize of a quarter of a circle, behind it; but in order to this, the door muſt open not inwards but outwards, of the granary, ſo that, as it falls back, it may be worked to and fro in the ſcreen; which muſt be exactly adapted to it in all parts of the circular ſide of the ſcreen, as well as at the top and bottom. But there muſt be a ſtep at about eight or ten inches diſtance from the wall, to prevent the doors falling back farther, that there may be room for a valve in the ſcreen to ſupply it with air: which air will be driven in by the door, through a hole made in the wall near the floor, into the main air-trunk, in which there muſt be another valve over the hole in the wall, to prevent the return of the air from within.

But with the view of facilitating the labour of frequently ſtirring and ventilating the grain, and of leſſening the expence of ſuch buildings, a member of the Society for the Encouragement of Arts, Manufactures, and Commerce, in a letter to Dr Templeman, recommends a new-invented granary, of which the following deſcription is given. It conſiſts, he ſays, of ſeven ſtories of floors, and may be built of any dimenſions, provided proper proportions are adhered to. The form of it is ſquare, ſuppoſe fourteen feet ſquare within the rooms or cells. The diſtance from the floor of one cell, to the floor of that above, is five feet; and the whole building ſhould ſtand on ſtrong poſts, more or leſs in number, according to the dimenſions, at the diſtance of ſix feet from the ground. The ſmall ſtairs, or rather ladder, to go to the ſeveral cells, muſt be fixed on the outſide of the building ſideways, with a leading rail, or rope, to prevent falling. The whole granary to be built of what is generally called brick noggin; that is, it is firſt framed in ſtrong timber work, and the interſtices filled up with brick. The floors, beams, and joiſts, are to be made ſtrong to bear the weight of the corn; and the inſide of the cells well lined with dry oak-board, cloſe jointed, and the outſide weather-boarded, the boards being ſtrongly nailed to the timber-work of the frame, and afterwards payed over with pitch. The floors of the cells are to be ſo contrived, as to ſhelve towards the middle, in which part is to be an aperture ſix inches ſquare, to be opened or cloſed by means of a ſliding ſhutter, which muſt have a long handle, reaching in a groove, without the granary. On three ſides of the rooms there ſhould be windows ſtrongly latticed, covered with wire, to keep out large inſects and birds, and with ſtrong ſhutters, to defend the corn from the weather. On the fourth ſide is a door to each room, to open from without. The windows are to be ſmall, and as cloſe as poſſible to the cieling. Over the upper room or cell is a loft, on the outſide of the door of which is fixed a crane, to be worked within by a winch and fliers. The uſe of the windows in the ſides of the rooms, is to give the corn all the benefit it can receive from the wind and freſh air. The door, when the cell is empty, admits the workman to ſweep, duſt, and clean it. The method of managing corn in this ſort of granary is as follows: when the wheat is properly cleaned, it is hoiſted in ſacks to the loft above, and emptied through a hole for that purpoſe in the floor. The apertures in the floors of the cells being all open (except the two undermoſt, which are cloſed by the ſliding ſhutters), the grain falls through till it reaches the undermoſt cell but one: when this is filled to the height of about two feet, which may be ſeen through the windows, the aperture in the floor of the next cell above is ſhut by its ſlider. This being filled in the ſame manner, the next above it is alſo ſhut, and ſo on till the whole are filled, if required, except the undermoſt, which is left empty. In this condition the corn is left for a week or more, if it was got in very dry. When it is to be ſtirred, the floor of the undermoſt cell is to be ſwept very clean, the door is again ſhut, and the ſlider in the floor above drawn back, which allows the corn to fall through into that cell. When the cell above is empty, the ſlider is again ſhut, the floor ſwept very clean, and the ſlider in the next floor over that is opened. In this manner they are all managed, till at laſt the uppermoſt cell remains empty; and the windows having all been open while the corn was falling from one cell to another, render great benefit thereto, by admitting a current of air to paſs through. Under the aperture in the floor of the lower cell, a proper ſcreen is fixed; at the end of this ſcreen is fixed a conductor or ſpout, to which a ſack is hung, its bottom reſting on a miller's hand-barrow; the ſlider is then drawn, and the corn let fall on the ſcreen, from which it runs into the ſack: when the ſack is full, the ſlider is for a moment ſhut, till another ſack, on another barrow, is put under the conductor; the workman then wheels the firſt ſack to the outſide of the granary, and, faſtening the crane rope to it, it is drawn up by another workman in the loft. The ſame method is purſued till the lower cell is emptied. If it is neceſſary to ſcreen all the corn at this time, a ſmall ſcreen is fixed under the aperture of the next cell to be emptied, ſo contrived, as to have a box at the back of it for receiving all the duſt, ſeeds of weeds, &c. that paſs between the wires; and this ſcreen is ſucceſſively fixed under every aperture as the cells are ſucceſſively emptied. After the firſt month, the corn need be ſtirred in this manner only once a fortnight, and after the firſt ſix months, only once a month, unleſs the weather ſhould prove in autumn very hot and damp. The advantages of this granary, as deſcribed by the inventor, are, that it is built at a ſmall expence; that it contains a great deal of grain in a ſmall compaſs; and that the grain is eaſily ſhifted and ventilated, without the tedious mode of turning it with ſhovels, or other ſimilar means.

However, the plan of a granary, taken from one built on his own eſtate, by a very reſpectable and intelligent gentleman in Cheſhire, who has found it to anſwer extremely well, it is conceived, by an able writer, will perhaps be preferable to the above, not only from its cheapneſs, but from its ſimplicity, and the eaſy mode by which the whole body of grain is ſtirred, and the air conveyed and circulated through every part of it, at whatever thickneſs or depth it is laid, and one floor only is neceſſary, however high the building may be. There can be no doubt, but that a granary of this nature may be very uſeful and convenient in many caſes.

This ſort of granary is ſhewn in *Plate Granary* on *Agriculture*, in which *fig.* 1. diſplays the front elevation of the building: *a* is the door into the lower part; *b*, the door into the loft above, to aſcend to which a ladder is neceſſary; *c*, a crane for hoiſting ſacks up from below; *d*, *d*, *d*, are air-holes for ventilation. At *fig.* 2. is ſeen a ſection or view of the inſide of the building; *a*, *a*, *a*, *a*, *a*, are wooden ſpouts, which reach from the air-holes on one ſide of the granary to thoſe on the other. Theſe ſpouts are formed of inch deal, about ſix inches broad, and made with an angle ſimilar to thoſe ſpouts that are employed to convey off the rain water from the eaſings of houſes. They are placed acroſs the granary with the angle upwards, as repreſented at *fig.* 3; *b*, *b*, *b*, are the ends of ſimilar ſpouts, which croſs the others, and alſo reach betwixt the air-holes on the other two ſides of the building, as ſeen at *fig.* 4; *c*, *c*, *c*, are half ſpouts, extending in the ſame manner to air-holes on each ſide. It is neceſſary that the air-holes ſhould decline outwards, in order to prevent the entrance of rain or ſnow in ſtormy weather; and they ſhould likewiſe be ſecured from inſects and vermin by wire cloth; *d d*, the floor of the granary, which is three yards ſquare, and divided each way into three hoppers, *e*, *e*, *e*, of one ſquare yard each, making in the whole nine hoppers, as ſeen at *fig.* 5; *f* is a large hopper, that encompaſſes all the reſt, and has a ſlider at *g* for opening occaſionally, as may be neceſſary in taking out the grain. And there is another ſmaller hopper *i*, which is ſuſpended to this by four iron haſps *k*, *k*, *k* *k*, that may be readily unfaſtened when required, from the ſquare deal box *o o*, fixed to the large hopper. Through the ſide of this box, the handle *h* of the ſlider muſt extend. This hopper is principally uſed for the convenience of taking out a ſmall quantity of grain, but is removed when a large quantity is to be taken from the granary; *m* is a ſmall loft into which the ſacks of grain are hoiſted, and emptied over the ſides or rails *n*, *n*, from which it falls down, and paſſes through the hopper *e*, *e*, till *f* is filled (the ſlider *g* being cloſed); and as the corn continues to be emptied from the loft, the granary is gradually filled until it is up to the top if neceſſary. The ſpouts being all inverted, as noticed above, and open below, it is obvious that, although the granary be filled to the top, the corn will not, like a fluid, riſe within the ſpouts above the level of their lower edges; and thus there will be a vacuum left within every ſpout, through which the air will freely paſs. Theſe ſpouts are placed three feet diſtant from each other, horizontally from angle to angle, and eighteen inches vertically; that is, from thoſe in one tire, to thoſe in another, which is the next, and croſſes it. The holes in the bottoms of the hoppers *e*, *e*, *e*, ſhould be ſo proportioned, that one may not give vent to the grain faſter than another; for which reaſon, the aperture of the middle one *a*, *fig.* 5, ſhould be the ſmalleſt, becauſe there is the leaſt obſtruction there. The apertures *b*, *b*, *b*, *b*, ought to be ſomewhat larger, as the grain will meet with ſome little obſtruction there; by the ſides of the large hopper; and the apertures or openings *c*, *c*, *c*, *c*, ſhould be the largeſt, as the obſtruction in the angles will be greater than in any other part of the work.

GRANASUOLA, in *Geography*, a town of Italy, in the department of the Amona; 6 miles N. of Faenza.

GRANATAN, a town of Saxony, in the circle of Erzgeburg; 12 miles N. E. of Freyberg.

GRANATARIUS, in *Middle Age Writers*, an officer in monaſteries who took care of the proviſions.

GRANATE, popularly called garnet, in *Natural Hiſtory*. See Garnet.

Granate *Paſte*. The counterfeit garnet in paſte, is formed with three different proportions of the ingredients, which are theſe:

Take prepared cryſtal two ounces, common red-lead ſix ounces, mangeneſe ſixteen grains, zaffer three grains; mix all well together; and put them into a crucible: cover it with a lute, and ſet it in a potter's kiln for twenty-four hours.

Or, take cryſtal two ounces, minium five ounces and a half, manganeſe fifteen grains, zaffer four grains; mix them well together, and leave room for their ſwelling in the pot; bake them twenty-four hours in a potter's kiln.

The laſt method is this: take cryſtal prepared two ounces, minium five ounces; mix them, and add manganeſe fifty-two grains, zaffer ſix grains; mix them well together, and let all be baked, in a pot well luted, in a potter's kiln for twenty-four hours.

The firſt of theſe makes a very handſome garnet of the common tinge; the ſecond, a deep one, with ſomething of a violet tinge, as many of the natural garnets have; but the third makes much the fineſt and brighteſt. Neri's Art of Glaſs, p. 134. See Glass and Paste.

GRANATINE, a name given by Kirwan to ſeveral triple compounds, profeſſedly of the granitic kind; but as it includes alſo combinations that have no more than one eſſential ingredient of granite (ſuch as the combination of quartz, jade, and garnet), it is obvious, that many rocks, thus united into one claſs, are far from having all the characters of granitic compounds.

GRANATITE. See Staurolite.

GRANATRISTUM, in *Surgery*, denotes a boil, or a carbuncle.

GRANATUM, in *Botany*, and the *Materia Medica*. See Punica.

GRANBY, in *Geography*, a townſhip of America, in Eſſex county, Vermont, containing 69 inhabitants.—Alſo, a townſhip in Hampſhire county, Maſſachuſetts, E. of S. Hadley, about 94 miles W. of Boſton; incorporated in 1768, and containing 768 inhabitants.—Alſo, a townſhip in Hartford county, Connecticut, on the line which ſeparates Connecticut from Maſſachuſetts; 18 miles N. of Hartford, and containing 2735 inhabitants.—Alſo, a ſmall town on the Congaree, in South Carolina; a place of conſiderable commerce, having a curious bridge, the arches of which are ſupported by wooden pillars, fixed by iron-work, in the ſolid rock, 40 feet high above the level of the water, with the centre arch 40 feet in the clear, for admitting the paſſage of large trees brought down by the flood.

Granby *Bay*, a bay on the N. coaſt of the iſland of Dominica. N. lat. 15° 42′. W. long. 61° 25′.

GRANCEY-en-Montagne, a town of France, in the department of the Coté-d'Or, and chief place of a canton, in the diſtrict of Dijon; 21 miles S. E. of Chatillon-ſur-Seine. The place contains 687, and the canton 4071 inhabitants, on a territory of 210 kiliometres, in 11 communes.

GRAND, a term rather French than Engliſh, though uſed on many occaſions in our language. It has the ſame import with *great*, being formed of the Latin *grandis*.

In this ſenſe we ſay, the grand maſter of an order, the grand maſter of Malta, of the free-maſons, &c.

So alſo, the grand ſignor, the grand viſier, &c. grandfather, grand-mother, &c.

In the French polity and cuſtoms there are divers officers thus denominated, which we frequently retain in Engliſh; as grand almoner, grand ecuyer, grand chambellan, grand voyer, &c.

Grand, Anthony Le, in *Biography*, who flouriſhed in the 17th century, was a native of Douay, and is denominated by ſome writers the "abbreviator of Deſcartes." He was author of many works on the ſubject of philoſophy, the chief of theſe are, "Inſtitutio Philoſophiæ ſecundum Principia Ren. Deſcartes," 4to. "Curioſus Naturæ Arcanorum Perſcrutator." Notes on the Phyſics of Rohault, which have gone through many editions; and "Hiſtoria Sacra a Mundo condito ad Conſtantinum magnum," which is ſaid to be his beſt performance. Moreri.

Grand, Joachim Le, a French political and hiſtorical writer, was born in 1653 at Thorigny, in Normandy. In early life he entered into the congregation of the Oratory, which he quitted in 1676, and went to Paris, where he engaged in the education of two young men of rank, and at the ſame time applied himſelf with all diligence to the ſtudy of hiſtory under the direction of father Le Cointe. He firſt appeared as a writer in the year 1688, in "A Hiſtory of the Divorce of Henry VIII. and Catharine of Arragon," in three vols. 12mo. The main object of this work is to refute certain facts and arguments contained in the two firſt books of Burnet's Hiſtory of the Reformation. This produced a controverſy between Le Grand and the Engliſh prelate, which has long ſince ceaſed to be intereſting. In 1691 he addreſſed three letters to the biſhop, on his critique of Boſſuet's Hiſtory of the Variations of Proteſtants. After this Le Grand was taken from his literary purſuits by the appointment of ſecretary to the abbè d'Eſtrees, in his embaſſy to Portugal. In this ſituation he continued till the year 1697. The leiſure which his diplomatic functions allowed was employed in tranſlations of Voyages and Travels from the Portugueſe. In 1702 he accompanied the ſame miniſter in Spain, where he remained about two years as ſecretary. Soon after this the marquis de Torci, miniſter of ſtate, took him into his ſervice, and employed his pen in drawing up ſeveral memorials concerning the Spaniſh monarchy, and other political topics, in which he was of great uſe to his patron, and acquitted himſelf with great ability. As an author his laſt printed work was a treatiſe "On the Succeſſion to the Crown of France." This was given to the world in 1718, and is reckoned a curious and uſeful performance. He died at the age of 80 in the year 1733. He had been poſſeſſed of church preferment, and had held, for a time, the office of cenſor royal of books. Moreri.

Grand, in *Geography*, is a denomination applied to a variety of places, as in the following inſtances.

Grand *Anſe*, or *Jeremie*, a well-built town in the weſtern part of the iſland of Hiſpaniola; the road of which is ſo bad, that veſſels, in order to eſcape the wind, are compelled to take ſhelter behind Cape Donna Maria. N. lat. 18° 15′. W. long. 74° 5′.

Grand *Bay*, a bay on the S.W. coaſt of Newfoundland, ſomewhat S. of Cape Ray.

Grand-*Bourg-Salagnac*, a town of France, in the department of the Creuſe, and chief place of a canton, in the diſtrict of Guéret. The place contains 2525, and the canton 7828 inhabitants, on a territory of 215 kiliometres, in eight communes.

Grand *Canal*, in Ireland, is an eſtabliſhment of which we have given ſome account in our article Canal, and have here to correct an error which crept into that account, in ſtating that the canal terminates in the Shannon at Tarmonbury, inſtead of Shannon-harbour, two miles above Banaghar. The branch to the Barrow joins that river at Athy; with a collateral branch from Low-town near Monaſtraven to Portarlington.

When the new part of the canal was finiſhed in 1804, from Tullamore to the Shannon, a general repair and deepening of the old parts took place, in which 3000 men were employed for expedition, and the whole line was ſcoured out, ſo that 60 ton boats might paſs. At Tullamore there are wharfs and warehouſes for goods, and alſo at Shannon-harbour, with inns and other accommodation for perſons on buſineſs.

The Doonare and Boulavoneen collieries in Queen's county, belonging to this company, were in February 1809 worked by 100 men, and they advertiſed for 200 more, in order to work 100 acres of a coal three feet four inches thick, which had then recently been laid dry: the canals and river navigations admitting of their being conveyed to Dublin, Limerick, Waterford, Athlone, &c.

Kildare aqueduct, eight miles from Dublin, is 100 feet high, according to M. De Luc, Geology, p. 320.

Grand-*Champ*, a town of France, in the department of Morbihan, and chief place of a canton, in the diſtrict of Vannes; ſeven miles N.N.W. of Vannes. The place contains 4139, and the canton 7850 inhabitants, on a territory of 202 kiliometres, in four communes.

Grand-*Couronne*, a town of France, in the department of the Lower Seine, and chief place of a canton, in the diſtrict of Rouen. The place contains 8000, and the canton 12,795 inhabitants, on a territory of 182½ kiliometres, in 13 communes.

Grand-*Fathers*, ſeveral large detached mountains of America, in the S.E. corner of Teneſſee, in which are the head-waters of French Broad, and Cataba rivers.

Grand *Forò*, a town of Africa, on the Slave Coaſt.

Grande *Iſland*, an iſland in the Atlantic, on the coaſt of Brazil; 16 miles long and two broad. S. lat. 23° 15′.

Grand *Iſland*, an iſland of America, in lake Superior, on the N. ſide of the lake.—Alſo, an iſland in Niagara river, about ſix miles long and three broad; its S. end is four miles N. of Fort Erie.—Alſo, an iſland at the mouth of lake Ontario, within the Britiſh territories; 20 miles long and at its greateſt breadth four miles.

Grand *Iſle*, a new county of America, in the N.W. corner of the ſtate of Vermont, incorporated in 1802, and including the towns of North Middle and South Hero, Vineyard (late iſle Motte), and Alburgh.

Grand *Iſles*, two large iſlands in lake Champlain, each about eight or ten miles long, and forming a townſhip belonging to Vermont.

Grand *Junction Canal.* To the full account which we gave of this very important inland navigation in our article Canal, we have here merely to add a few particulars which have occurred ſince that account was printed. The act of the 50th Geo. III. for the Grand Union canal provides, that a canal with locks is to be ſubſtituted for the railway-branch from Gayton to Northampton, in order to open a communication by water, from the head of the new navigation, the deſign for the continuation of the Leiceſterſhire and Northamptonſhire Union canals further ſouth than Market Harborough, where it now terminates, being dropt, in conſequence of the adoption of the Grand Union above-mentioned, which will connect the above canal with the Grand Junction. The three aqueduct arches over the Ouſe at Wolverton having been made flat elliptical, inſtead of the curves of equilibration, and the foundation alſo inſufficient, they gave ſigns of great inſecurity immediately on their centres being ſtruck, and in February 1808 two of them actually fell in and emptied the canal, as far as the ſtop-gates: fortunately, the old line of locks acroſs the valley had not been diſturbed, and the trade has ſuffered no interruption in conſequence. A caſt-iron aqueduct on brick and ſtone piers is now ſubſtituting for theſe three arches, under the direction of Mr. Benjamin Bevan, who is now the engineer to the company. In 1807 a new reſervoir was compleated near the ſide-ponds on the northern ſide of the Tring ſummit, for ſupplying water to the locks below the ſide-ponds in dry ſeaſons.

In examining the ſtrata and ſprings on the north ſide of the chalk ſummit, between Tring and Wendover, with a view to better ſupplying the Wendover branch and ſummit-level with water, Mr. Bevan diſcovered, that different water-tight beds in the lower chalk held up ſprings a conſiderable height above the canal, owing to their dip to the ſouthward; and in order to avail himſelf of this water, a ſough or tunnel was began in the upper bank of the canal near Wendover, and has been driven about half a mile ſouthward, interſecting different ſtrata of chalk from beneath, and increaſing in its ſupply of water as it proceeded; but obſerving that the principal vent of this water was in the winter and early ſpring months, when the other ſources were more than ſufficient for the ſupply of the canal, it occurred to that ingenious gentleman to place a ſtrong and water-tight valve in the moſt favourable part of this tunnel, which, as ſoon in the autumn as the canal is amply ſupplied from its other feeders, is ſhut, and kept ſo, until theſe begin again to ſlacken in their ſupply; the water in the immenſe planes of theſe beds of chalk, in the mean time accumulating, as in a vaſt ſubterranean reſervoir, the ſprings riſe to the level which they originally did before this tunnel was begun, about 20 feet above the canal; and for many weeks after the opening of the valve, in the beginning of ſummer, they pour forth a moſt ſurpriſing ſtream of water into the canal, which otherwiſe would have vented miles off in the chalk vallies, or ſlowly have made its way down through the joints and fiſſures in the ſtrata to ſprings at the bottom of the chalk, which vent below the level of the canal.

In 1808 a twelve-horſe ſingle Bolton's ſteam-engine was erected near Naſh-mill, in Hertfordſhire, to lift the water again, the riſe of four locks, for better ſupplying the mills during ſeven or eight months of the year. The company, in 1806, cauſed boats to be fitted up for conveying fat ſheep alive, in tiers one above another, from diſtant places in the county, to the London markets, inſtead of fatiguing them by driving along the roads, the ſcheme of thus bringing oxen having been previouſly tried, and found not to anſwer; but after a fair trial, the expences were found to over-balance the advantages expected from this alſo; we are ſorry alſo to add, that the cattle-market at Paddington has failed, and that the pens erected for it by the company have been ſold and removed.

The limited quantity of coals brought to Paddington, or within 20 miles of London by this canal, now pay a duty of 10*s.* 9¾*d* per ton (of 20×112lb.), which is equivalent to the duty on Newcaſtle coals in the Thames: in conſequence of this heavy and oppreſſive duty, many waggons and carts are employed in fetching coals by land, from the next wharf beyond the limited diſtance, near Watford. The Grand Union canal above-mentioned is begun, and is to join this canal near the S.W. end of the Braunſton tunnel. The deſign of a branch from near Tring, through Ayleſbury and Thame, to the Thames and Iſis navigation and Wilts and Berks canal near Abingdon, has been again revived, and it ſeems probable, that an act for that purpoſe will paſs in the enſuing ſeſſions of parliament (1811).

Towards ſupplying water to the inhabitants near Paddington, a transfer of the company's rights has been made to a ſeparate water-company, which is expected to be confirmed by parliament in the enſuing ſeſſions.

In November 1806, the company declared the firſt half yearly dividend of 1½ *per cent.* on the original ſhares, which has regularly increaſed to 3 *per cent.* half-yearly, excluſive of property tax. The affairs of the company ſeem now faſt retrieving from the effects of their great miſmanagement for many years after its eſtabliſhment, and to be now in a very proſperous ſtate; the ſhares (of 100*l.*) were, in September 1810, reported to be currently ſold at 302*l.* each! although, at one period, the ſame could with difficulty be diſpoſed of at 65*l.* to 70*l.* each: ſuch are the effects of good or bad management, and of abilities and integrity in thoſe entruſted with the direction and management of an immenſe concern like this, in inſpiring confidence in commercial men to enter into trade and ſpeculations connected with the canal, and in capitaliſts to inveſt their money in the company's ſhares. A reſolution of the general aſſembly of proprietors, on the 7th of June 1803, for appointing a general ſuperintendant of their concerns, principally led to this beneficial change. On the 11th of June following, Charles Harvey, eſq. was appointed to this office by the committee, and, after much oppoſition from certain powerful individuals, was, on the 11th of July, confirmed therein, by a general aſſembly called for the ſpecial purpoſe.

GRAND *Key*, a ſmall iſland among the Bahamas. N. lat. 26 54′. W. long. 77° 48′.

GRAND *Lake*, a lake of Louiſiana. N. lat. 32°. W. long. 93° 5′.—Alſo, a lake in the province of New Brunſwick, near the river St. John's, ſaid to be 30 miles long, eight or ten broad, and in ſome places 40 fathoms deep.

GRAND *Luce, Le*, a town of France, in the department of the Sarthe, and chief place of a canton, in the diſtrict of Saint-Calais; 14 miles S.E. of Le Mans. The place contains 2045, and the canton 10,493 inhabitants, on a territory of 227½ kiliometres, in 8 communes.

GRAND *Manen Iſland*, an iſland of the Atlantic ocean; 6 miles S. by S.E. of Campo Bello iſland, oppoſite to Papamaquoddy bay on the eaſtern border of the United States.

GRAND *Ridge*, is a term often uſed, (ſee our article CANAL,) for the water-head, or ſummit line, acroſs an iſland or continent, from whence the rain waters fall by oppoſite courſes to the ocean. It reſults from the admirable ſyſtem of vallies, which the great Creator has ſpread over the whole face of the earth, leaving no part, perhaps, originally of the ſurface, without a deſcent and out-fall to the ſea; that the ridges, or ſummit-lines, form a ſyſtem not leſs beautiful and perfect than the vallies; and whence it happens, that, from any hill whatever, it is practicable to mark on a good map, and to travel to every other hill in the ſame iſland or continent, however large, without croſſing any running water, however ſmall, but conſtantly to paſs along a ridge or waterſhead; whence the waters on the ſurface fall oppoſite ways from your route. It ſeems ſurpriſing, that no one has attempted to illuſtrate this ſubject by a good map, ſhewing all the connections and windings of theſe ridges in England, or even any local diſtrict, until of late, that Mr. Farey has prepared a ſquare of map, including Derbyſhire, ſhewing the ridges, and the ſituation of all the hills and principal eminences upon them, which is intended to accompany his report to the Board of Agriculture on that intereſting diſtrict.

The triangular form of the Britiſh iſland, and the ſituation of the two principal rivers, the Thames and the Severn, (or rather the Briſtol channel,) occaſion the grand ridge of England to divide into two branches on the Chalk Downs, a few miles N.E. of Devizes; one of which, (the ſouth-weſtern,) proceeds to Rundaway-hill, and croſſes the deep cutting of the Kennet and Avon canal, near to Devizes, near Eaſt Lavington, Warminſter, Wincanton, Beaminſter, Crewkerne, Chard, &c. by a moſt circuitous route, paſſing almoſt to the north and to the ſouth coaſts alternately, until it reaches the Land's End in Cornwall: having, in this long route, probably deſcended to no lower ſtrata than the red ground or marle, of which we ſhall ſpeak further preſently.

The other, or ſouth-eaſtern branch of the grand ridge, proceeds along the chalk and the clays and ſands above it, acroſs the deep-cutting of the Kennet and Avon canal, near Burbage, by High-clerc, (near which it probably occupies the higheſt ſtratum in the whole Britiſh ſeries,) near to Alton and Haſlemere, when it ſoon deſcends off the chalk into the great ſouthern denudation, (ſee Philoſophical Magazine, vol. xxxv. p. 130.), and purſues the under meaſures, through the wealds of Suſſex and Kent, by Alford, Leith-hill, Hands-croſs, (on the London and Brighton roads, being there on the loweſt ſtratum but one which appears in that road,) by Turner-hill, Nutley, Crowborough, Rotherfield, Wadhurſt, Tenterden, Shadoxhurſt, Lympe (near Hythe), where it again aſcends the edge of the chalk, and proceeds on it by Paddleſworth, Swingfield, and Lydden, to the coaſt at King's Down, near Walmer caſtle.

From the point of branching, N.E. of Devizes, as above deſcribed, the grand ridge follows the chalk northward by White-horſe hill, near Cherhill, &c. till within a few miles of Swindon, when it turns to the N.W., and deſcends to the marle, and other ſtrata below the chalk, croſſing the Woburn ſand ſtratum, not far from Wooton-Baſſet: and, paſſing to the Bath free-ſtone range, it croſſes the Salperton tunnel, on the Thames and Severn canal, and proceeds near to the weſtern edges of the ſame ſtrata, by Charlton-Kings, near Cheltenham, Stanway-hill, Broad-way-hill, Lemington-hill, Long-Compton-hill, and Epwell; ſoon after which, the grand ridge begins to leave the free-ſtone, and take to the dark blue clays, &c. under it, except croſſing ſome points of the ſtone, and traverſes the Fenny-Compton tunnel, on the Oxford canal; thence by Hellidon, and near Daventry, it croſſes the Braunſton tunnel, on the Grand Junction canal, at Weſt-Haddon, and at Huſband's-Boſworth, the tunnels of the Grand Union canal; when, turning north-weſt, the ridge paſſes Gilmorton; and not far from Lutterworth it croſſes the Lias clays and lime-ſtone ſtrata, and deſcends to the red marle (above mentioned), and quickly, by a great fault, or ſudden lift of the ſtrata, is brought upon the coal-meaſures of the Bedworth-field, and croſſes the deep cutting of the Coventry canal, through Bedworth town, acroſs the late ſir Roger Newdigate's canal, and ſweeps round to the weſt, ſouth-weſt, and ſouth, to Kenilworth; when, having croſſed another fault, and got again upon the red marle, it croſſes the deep-cutting of the Warwick and Birmingham canal, near Baddeſley-Clinton, and of the Stratford canal, near Hockley; thence by Aſhley-heath, and croſſes the Weſt-heath tunnel of the Worceſter and Birmingham canal, and the Lapal tunnel of the Dudley canal: after which, the grand ridge croſſes the baſaltic hills between Rowley and Dudley, (which belong to the red marle ſtrata,) and, deſcending to the coal-meaſures, croſſes the Dudley tunnel N.W. of that town, and proceeds by Sedgley; then croſſing an erect and denudated patch of the yellow lime-ſtrata, it croſſes the deep-cuttings of the Old Birmingham canal, the Wyrley and Eſſington canal, and of the Staffordſhire and Worceſterſhire canal, all near Wolverhampton town; then by Taterhall, Wrotteſley, Blimhill, Cowley, Wooton, (near Eccleſhall), Broughton, Aſhley, Maer, Madeley-park, to Keeſe, (near Newcaſtle-under-line,) where it has again got upon coal-meaſures, by Bignole-hill, and acroſs the Harecaſtle tunnel, on the Trent and Merſey canal, by Golden-hill, Wickinſtone rocks, and, croſſing an immenſe fault, deſcends to the lime-ſtone ſhale, (ſee Mr. Farey's ſection in *Plate* II. vol. xxxi. of the Philoſophical Magazine,) on Biddulph Moor; thence paſſes the top of the Great Rudyard reſervoir, to Gun-hill, and croſſing to High Roches rocks, it there aſcends the firſt grit; then croſſes a ſmall trough of the firſt coal-ſhale and ſecond grit, and deſcends again to the firſt grit, or Ramſhaw rocks, and ſtill further, on the lime-ſtone ſhale, at the Royal Cottage, along which it proceeds to the N.W. ſide of Flaſh, and then aſcends the firſt grit again, on South-Axe-edge-hill; it again deſcends to the ſhale lime-ſtone in croſſing Middle and Great Axe-edge-hills; from whence it aſcends acroſs the firſt grit and firſt coal-ſhale, and aſcends the ſecond grit on Thatch Marſh; this it purſues to the north of the Macclesfield and Buxton road, and then turning N.E. again deſcends to the lime-ſtone ſhale, and follows it acroſs the Mancheſter and Buxton road; ſoon after, it aſcends the firſt grit, and firſt coal-ſhale, on Comb's-moſs, and again deſcends to the ſhale, paſſes Sitting-low, (1½ mile S.E. of Chapel-en-le-Frith,) when, turning eaſtward, it croſſes the Great lime-ſtone fault, (N. of Dove-holes,) and is found upon the third lime-ſtone, on which it croſſes the quarries and rail-way of the Peak-Foreſt canal; ſoon after, it paſſes over the baſſet-edge of the third toad-ſtone, and deſcends to the great fourth lime-ſtone in Peak-Foreſt, which is probably the *loweſt* ſtratum, to which the grand ridge paſſes in its route through England; this lime-rock having been eſtimated to be four miles at leaſt of perpendicular thickneſs below the top of the chalk, from whence we commenced our deſcription; much the greater part of this vaſt ſeries of ſtrata having in this route along the grand ridge been loſt ſuddenly by perpendicular lifts of the ſtrata or faults, which, in proceeding to this point by more favourable routes, might have been ſeen baſſeting in ſucceſſion. For about one and a half mile the ridge proceeds upon the fourth lime, then again aſcends a point of the third toad-ſtone and third lime, to the village called Sparrow-pit, in the Mancheſter and Caſtleton road, where it again croſſes the great fault and aſcends to the lime-ſtone-ſhale on Ruſhop-edge, whence it proceeds northward, and after croſſing the Bridle-road from Hayfield to Edale-chapel, it aſcends the firſt grit on Edale rock, and proceeds acroſs the moſſes on Kinder-ſcout hills; theſe it leaves at their N.W. corner, and croſſes the moſſes on the ſhale, and the ancient Bridle-road called Doctor-Gate, from Gloſſop to Aſhop-Dale; it then aſcends the firſt grit again on ſhelf-ſtones, and follows the ſame to Wain-ſtones and Blakelow-ſtones, which ſeems to be the higheſt land in Derbyſhire, it then paſſes N. E. by Round-hill, and aſcends to the firſt coal-ſhale, croſſes the Mancheſter and Peniſtone-road at Lady-croſs; where, turning N. W. it aſcends the ſecond grit rock, and proceeds by Dean and Bretland Edges, to croſs the Gloſſop and Huddersfield road, on the bogs upon this rock on Holme moſs; from hence the ridge, after ſome diſtance, again deſcends to the firſt coal-ſhale, the firſt grit, and to the limeſtone-ſhale, croſſing the Stanage funnel on the Huddersfield canal near Marſden; the ridge then proceeds acroſs Black-ſtone-edge, and croſſes the deep-cutting of the Rochdale canal, near the village of Huddersfield, (which has improperly been ſaid in the population accounts of 1801, to be a *town* containing 10,671 perſons!) the ridge then paſſes Holme on the Burnley and Halifax road, whence it proceeds, and near Colne comes again upon coal-meaſures, which are, however, loſt again at the great fault, in which part of the Foulridge tunnel on the Leeds and Liverpool canal was driven, and which occaſioned the extraordinary trouble and expence attending that tunnel, which is mentioned in our article CANAL. From hence the grand ridge proceeds, by Barnoldſwick, Weſt Marton, near the Cold-Coniſtora, E. of Settleton lime-ſtone, over Pennigant-hill, Snays-fell, Nine-ſtandards, Kelton-fell, Lune-foreſt, Scordal-head, Milborn-foreſt, Aldſtone-moor, (lime,) Hartſide-croſs, Geltſdale-foreſt, Talkin, and croſſes the Roman or Picts wall on the E. ſide of Upper Denton, and ſoon after it enters Roxburghſhire in Scotland; through which it is much eaſier to trace this grand ridge than in England, it forming often the boundaries between the Scotch counties, to which this ridge and its collateral ridges are much better adapted than the rivers and brooks, which have generally been choſen as boundaries, both as being more permanent, and not liable to the changes which ſtreams of water are undergoing in the bottoms of vales, and avoiding thoſe diſputes reſpecting, and the delay of making and improving bridges, fords, navigations, mills, &c. owing to the rivers being part in one county and part in another, and by which alſo many of the moſt conſiderable towns are ſplit into two or more counties, to the no ſmall inconvenience of their inhabitants, in judicial and other county matters.

GRAND *River*. See OTTAWA and OUSE.—Alſo, a river of Africa which runs into the Indian ſea, S. lat. 2° 8′.

—Alſo, a river of Sicily, which runs into the Mediterranean on the N. ſide of the iſland, N. lat. 38° 3′. E. long. 14° 54′. —Alſo, a river of America, which runs into the Miſſouri, N. lat. 38° 56′. W. long. 93° 25′.—Alſo, a broad river of America, which diſcharges itſelf into lake Michigan, N. lat. 43° 25′. W. long. 85° 35′.—Alſo, a river of America, which runs into lake Erie, N. lat. 41° 55′. W. long. 81° 8′.—Alſo, a river of Canada, which runs into the Detroit, N. lat. 42° 34′. W. long. 82° 42′.—Alſo, a river of Canada, which runs into the St. Laurence. N. lat. 47° 3′.

GRAND *River*, or *Rio grande*, a river of Africa, which runs into the Atlantic, near the Biſſagos iſles, N. lat. 11°. W. long. 14° 30′.

GRANDE *Seaux*, an Indian nation, inhabiting a territory of the Miſſouri, and able to furniſh 800 warriors.

GRAND *Surry-Canal.* This canal is yet in the ſame ſtate, nearly, as when our account of it in the article CANAL was written, in 1805, except, that about two miles in length of it, at its N. E. end, has been brought into uſe, ſince the Croydon canal has been completed; and that the dock for ſhips, at its entrance from the Thames, was completed and opened in June 1807, and has anſwered ſo well to the proprietors, that in the laſt ſeſſions of parliament, they made an unſucceſsful attempt to obtain power for a further extenſion of them. In February, 1809, this company determined on erecting a ten-horſe ſteam engine on the banks of the canal, by the Deptford road, for ſupplying the neighbouring inhabitants with water, intending to let the ſurplus power of this engine to ſome manufacturers.

GRAND *Traverſe*, a range of iſlands, conſiſting of huge rocks in lake Michigan.

GRAND *Trunk Canal*, is a name commonly applied to the Trent and Merſey canal, which ſee in our article CANAL.

GRAND *Union Canal.* In the ſeſſions of parliament, 1810, (50 Geo. III.) an act paſſed for making the Grand Union canal, the general direction of which is about S.W. 23½ miles, in the counties of Leiceſter and Northampton, being conſiderably elevated, and croſſing the grand ridge of the iſland twice, by tunnels, its middle part for about half its length ſkirting near to the ridge on its weſtern ſide, and the two ends being on the eaſtern ſide of the ridge. Its objects are the completing of the long-deſired water-communication between the Trent river and the many canals which connect therewith, in Derbyſhire, Nottinghamſhire, and Leiceſterſhire, and the Grand Junction canal, and through it to the metropolis, without making the enormous circuit by Burton, Fradley-heath, near Litchfield, Tamworth, Atherſtone, Nuneaton, and Braunſtone, which at preſent goods, coming by water from Leiceſter, Nottingham, and Derby muſt do; it is intended alſo to ſuperſede the neceſſity for the ſouthern part of the Leiceſterſhire and Northamptonſhire Union canal, between Market-Harborough and Northampton, which on account of its difficulties has never been attempted; the preſent rail-way branch between the Grand Junction and Northampton is intended to be changed for a canal with locks, by which means the people of Northampton will have a water-communication with Market-Harborough, Leiceſter, &c. with only about 14 miles longer diſtance than the Leiceſterſhire and Northampton Union would have been, if the ſame had been completed according to its original act. Market-Harborough and Daventry are the only conſiderable towns near the line of this canal, which commences in the Leiceſterſhire and Northamptonſhire Union canal near Gumley, and terminates in the Grand Junction canal near Buckby-wharf, near the S. E. end of the Braunſtone tunnel. From Gumley in ¼ mile is a riſe of 76 feet by 12 locks; and thence to Watford, 20 miles are level, then in ¼ mile is a fall of 53 feet by eight locks, and thence to the Grand Junction canal about three miles are level; near Huſband's Boſworth is a tunnel of about 1120 yards long, and near Crick another of about 900 yards long. Near Crick it is propoſed to make a reſervoir of 60 acres above the canal, but below its level, ſo that the ſurplus water collected from other parts of the canal in rainy ſeaſons can be here reſerved, to be pumped up when wanted.

The width of the canal at top is 42 feet and 14 at bottom, and its depth of water five feet; the locks are 82 feet long and ſeven wide, calculated for 25 ton boats. This line was firſt ſurveyed by Mr. James Barnes in 1803, and by Mr. Benjamin Bevan in 1808 and 1809, and the latter is appointed engineer for the execution of the work.

GRAND *Weſtern Canal*, is ſo denominated in an act which paſſed in the year 1796, as mentioned in our article CANAL, but under which no progreſs had then been made. In April 1810, it was reported, that a beginning had at length been made on the ſummit level, in Holcomb, Devon. A much larger canal, capable of conveying ſhips from the Briſtol channel to the ſouth coaſt, has been ſome time in agitation, for avoiding the very circuitous and tedious navigation round the Land's End; which, however deſirable, is ſcarcely practicable, we incline to think, for want of water.

GRAND *Aſſiſe, in Law.* See ASSISE.

GRAND *Cape.* See CAPE and ATTACHMENT.

GRAND *Couſtumier, le*, an ancient book of very great authority, which contains the ducal cuſtoms of Normandy.

GRAND *Days.* See DAY, in *Law.*

GRAND *Diſtreſs, diſtrictio magna*; a writ of diſtreſs, ſo called on account of its extent, which reaches to all the goods and chattels of the party within the county.

This writ lies in two caſes: either when the tenant or defendant is attached and appears not, but makes default: or where the tenant or defendant hath once appeared, and after makes default. On ſuch occaſions, this writ lies by common law, in lieu of a petit cape.

GRAND *Elixir, guard, jury, larceny, prior, provoſt of France; ſerjeanty.* See ELIXIR, GUARD, &c.

GRAND *Guſto*, in *Painting.* See GUSTO.

GRANDE, in *Geography*, a town of Norway, in the dioceſe of Drontheim; 21 miles N. W. of Drontheim.

GRANDEE is underſtood of a lord of the firſt rank or prime quality.

In Spain, the term grandees is uſed abſolutely to denote the prime lords of the court, to whom the king has once given leave to be covered in his preſence: there are ſome grandees for life only; made by the king's ſaying ſimply, be covered. Others are grandees by deſcent; made by the king's ſaying, be covered for thyſelf and heirs. Theſe laſt are reputed far above the former.

There are ſome who have three or four grandeeſhips in their family.

GRAND-GOR. A Scotch appellation for the venereal diſeaſe.

In the Philoſophical Tranſactions, N° 469. ſect. 5. we have a proclamation of king James the IVth of Scotland, ordering all who had this diſeaſe, or who had attended others under it, forthwith to repair to an iſland in the Frith of Forth. If the grand-gor was the pox, and this diſtemper came into Europe at the ſiege of Naples in 1494, it muſt have made a very quick progreſs to cauſe ſuch an alarm at Edinburgh in 1497.

GRANDI ERCOLE, in *Biography*, whom Vaſari calls Ercole da Ferrara, was a painter of the early ages in the art after its revival. He was a diſciple of Lorenzo Coſta, whom he afterwards ſurpaſſed in excellence, and at whoſe death he was appointed to compleat the work of the Crucifixion, begun by the former for Domenico Garganelli, in the church of St. Pietro in Bologna, by which he gained great reputation for the excellence of the colour, and the truth and force of expreſſion; although it is wrought in the dry ſtyle of Mantegna and P. Perugino. When unfortunately the chapel was deſtroyed, that part of the picture which was preſerved was placed in the palace Tanara. His peculiar ſhyneſs of manner made him many enemies in Bologna. He therefore quitted it and went to Ferrara, where he produced many works which are very ſcarce now. His fondneſs for wine ſhortened his life, and he died at the age of 40 in the year 1531.

GRANDI, FRANCIS LEWIS, who flouriſhed in the latter end of the 17th, and the commencement of the 18th centuries, was born in 1671 at Cremona. He was diſpoſed to a ſtudious life, and choſe the profeſſion of theology, in order that he might freely indulge his inclination. He entered into the religious order of Camaldolites, at Ravenna, at the age of 16; and on this occaſion he relinquiſhed his own Chriſtian name, and received that of *Guy*. He became, in the early progreſs of his ſtudies, diſtinguiſhed for his proficiency in the different branches of literature and ſcience, and being diſſatisfied with the Peripatetic philoſophy of the ſchools, he was ambitious of contributing to introduce a more rational ſyſtem. With this view he offered himſelf as a candidate for the vacant profeſſorſhip of philoſophy in the ſchool of Florence, and obtained his object, though not without the moſt determined oppoſition from the prejudiced adherents to the old opinions. He now applied himſelf to the introduction of the Carteſian philoſophy, while, at the ſame time, he became zealouſly attached to mathematical ſtudies. The works of the great Torricelli, of our countryman Wallis, and of other celebrated mathematicians, were his favourite companions, and the objects of his familiar intercourſe. He publiſhed a treatiſe to reſolve the problems of Viviani on the conſtruction of arcs, which he dedicated to the grand duke Coſmo III., who was ſo delighted with the performance, that he appointed the author profeſſor of philoſophy in the univerſity of Piſa. From this time Grandi purſued the higher branches of mathematics with the utmoſt ardour, and had the honour of ranking the ableſt mathematicians among his friends and correſpondents. Of the number may be named the illuſtrious Newton, Leibnitz, and Bernouilli. By his life of St. Peter Damiano, publiſhed in 1702, and his examination of the legends of St. Romauld, he gave offence to the bigots of his community, and was depoſed from the dignity of abbot of St. Michael at Piſa; but the grand-duke had too liberal a mind to be offended; and to ſhew the eſtimation in which he held the philoſopher, he immediately appointed him his profeſſor of mathematics in the univerſity; which, perhaps, led to his re-inſtatement in the abbacy. He now reſolved ſome curious and difficult problems for the improvement of acouſtics, which had been preſented to the Royal Society in Dublin, and having accompliſhed his object, he tranſmitted the ſolutions, by means of the Britiſh miniſter at the court of Florence, to the Royal Society at London. The principal work of Le Grandi was "A Treatiſe on Series and Infiniteſimals." He appeared likewiſe as the defender of Galileo's doctrine reſpecting the earth's motion, and obtained a complete victory over thoſe who oppoſed it. He was deeply verſed in ſubjects of political economy, and various diſputes were referred to his deciſion reſpecting the rights of fiſhery, &c. He was appointed commiſſioner from the grand-duke and the court of Rome jointly, to ſettle ſome differences between the inhabitants of Ferrara and Bologna, concerning the works neceſſary to preſerve their territories from the ravages of inundation. For theſe and other important public ſervices he was liberally rewarded by his employers. Reverting to his literary labours, Le Grandi engaged in a conteſt with Le Ceva, on the ſubject of the philoſophy of the ancients and moderns. This diſcuſſion was occaſioned by a preface to a Latin poem by Le Ceva, in which he maintained that none but heretics would renounce the philoſophy of Ariſtotle. The remainder of his life this great man ſpent in mathematical purſuits, and in the publication of works of ſcience, which are too numerous to be recited here. He died at the age of ſeventy-two in the year 1742. Moreri.

GRANDIER, URBAN, was born in the latter part of the 15th century. His father, a notary-royal at Sablé, gave him a good education, and introduced him while young among the Jeſuits at Bourdeaux, to whoſe friendſhip he recommended himſelf, as well by his natural genius and fine underſtanding, as by his diligence and proficiency in his ſtudies. Conceiving highly of his talents, the fathers of the college gave him the living of St. Peter, at Loudun, of which they were the patrons, and procured him a prebend in the church of the Holy Croſs. Theſe benefices rendered him the object of jealouſy with eccleſiaſtics, which was ſtill farther heightened by the accompliſhments of his perſon and the elegance of his manners. With his friends he was eaſy, facetious, and agreeable, but extremely haughty towards thoſe whom he regarded as his enemies. Some of his brethren of the clergy he had exaſperated, by the arrogance with which he triumphed over them, upon gaining certain ſuits in the eccleſiaſtical court, and he raiſed a hoſt of foes by his reported ſucceſsful gallantries with the ladies, to the great mortification of diſappointed rivals, incenſed fathers and huſbands. A league was formed with a view of driving him entirely out of Loudun: a heavy charge of debauchery, irreligion, and impiety was laid againſt him, in the biſhops' court of Poictiers, which produced, firſt, a ſuſpenſion of the prieſts' functions; and afterwards he was condemned to reſign his benefices, and to the practice of penance and mortification. From a ſentence ſo ſevere, Grandier appealed to the archbiſhop of Bourdeaux, by whoſe means he was acquitted, and even allowed to ſue for the recovery of damages, and the reſtitution of the profits of the benefices during his ſuſpenſion. The archbiſhop, a friend to peace, earneſtly recommended him to change his reſidence, but he was incapable of renouncing his favourite paſſion, revenge. He returned to Loudun, bearing in his hand a branch of laurel, and in his mind a fixed reſolution of humbling his enemies. They were equally bitter, and ſmarting under the laſh of the victor, they ſet about means to compaſs his deſtruction. A prieſt, named Mignon, deviſed a plan, which ultimately enabled them to gratify all their malignity. He trained up nuns in the Urſuline convent at Loudun, to act the part of women poſſeſſed with evil ſpirits: theſe were inſtructed to accuſe, in their frantic fits, Grandier of having ſubjected them to demoniacal influence. At firſt he was indifferent to the reports, conſidering the buſineſs as a mere farce. It had, however, a moſt tragical concluſion. Grandier, at length, finding, from the effects produced upon the credulous devotees, that matters were taking a ſerious turn, appealed to the magiſtrates, conſcious of his own innocence, and requeſting them to take cognizance of the affair. They began the inveſtigation, and were ſatisfied that the whole was the effect of trick, but when they attempted to interpoſe their authority, and prohibit the continuance of ſuch diſgraceful proceedings, the prieſts who had patronized and inſtructed the women, and who were bent upon the deſtruction of Grandier, diſowned their juriſdiction and defied their power. An application was made to the archbiſhop of Bourdeaux, who employed phyſicians to examine into the caſe, and by their reports no doubts were left in the mind of the prelate, that the buſineſs was founded on the moſt groſs and ſcandalous impoſture. Upon this the archbiſhop iſſued an order, the ſeverity of which put the whole legion of devils to flight. After a time the ſcheme was renewed, and the authors of it contrived to engage cardinal Richlieu to favour their malignant deſigns. For this purpoſe the monks of Loudun wrote to father Joſeph, one of their fraternity, informing him that Grandier was author of a ſatire, entitled "The Shoemaker's wife of Loudun," containing reflections on the cardinal's birth and perſon, which had excited in the boſom of the cardinal the ſharpeſt ſtings of reſentment. Believing that the information was correct, he determined to make the ſatiriſt feel the full weight of his vengeance. Grandier was arreſted and brought to trial, and after a tedious proceſs, in which the farce of exorciſing the poſſeſſed was ſeveral times repeated, and the judge's partiality and tyranny diſplayed in the moſt glaring light, "upon the depoſition of Aſhtaroth, a devil of the order of Seraphim, and the chief of the poſſeſſing demons, and upon the depoſitions of the nuns, who pretended to be poſſeſſed of devils, the commiſſioners gave judgment, declaring Grandier duly attainted and convicted of the crime of magic, ſorcery, and poſſeſſion, happening by his means in the perſons of ſome of the Urſaline nuns, &c. for the reparation of which he was condemned to an amende honourable, and to be burnt alive with the magical characters." Grandier, innocent of the charge, heard the ſentence without any emotion, and afterwards ſuſtained the torture, ordinary and extraordinary with aſtoniſhing fortitude, never ſuffering one repining expreſſion againſt his enemies to eſcape him through the whole ſcene. The laſt words which he was heard to utter previouſly to the flames reaching his vital parts, were in ſupplication to God, to whoſe mercy he recommended himſelf. Such was the fate of Urban Grandier, whoſe pride and paſſions appear to have been cauſes of the conſpiracy to which he fell a victim, and whoſe hiſtory exhibits a memorable example to ſhew to what pitch of folly and madneſs the fury of an incenſed cabal, the revenge of a miniſter, and the proſtitution of a judge, may be wrought up. The relations of the caſe is given in "The Hiſtory of the Devils of Loudun," firſt publiſhed at Amſterdam in 1693, and which has been frequently reprinted. As an author Grandier is known by a funeral oration for Scævola de St. Martha, which is highly commended for the maſterly ſtrokes of eloquence interſperſed through it. Moreri.

GRANDINES, in *Surgery*, ſmall tumours on the eyelids.

GRANDMONT, in *Geography*, a town of France, in the department of the Upper Vienne, near which was an abbey, ſuppreſſed in 1769; 15 miles N.E. of Limoges.

GRANDOLA, a mean town of Portugal, in the province of Eſtramadura, containing 800 houſes, ſituated between Cadaon and the ſea-coaſt. Behind it is the Sierra de Grandola, that proceeds in two ranges, one behind the other, from eaſt to weſt; the town is 27 miles S.E. of Setuval.

GRANDPRE', a town of France, in the department of the Ardennes, and chief place of a canton, in the diſtrict of Vouziers; 33 miles E. of Reims. The place contains 1350, and the canton 8617 inhabitants, on a territory of 242½ kiliometres, in 14 communes.

GRANDRIEUX, a town of France, in the department of the Lozere, and chief place of a canton, in the diſtrict of Mende; 10 miles N.W. of Langogne. The place contains 1657, and the canton 5389 inhabitants, on a territory of 235 kiliometres, in 7 communes.

GRAND-SERRE, Le, a town of France, in the department of the Doubo, and chief place of a canton, in the diſtrict of Valence. The place contains 1491, and the canton 6189 inhabitants, on a territory of 232½ kiliometres, in 10 communes.

GRANDVILLE, or Granville, a town of France, in the department of the Channel, and chief place of a canton, in the diſtrict of Avranches, 12 miles N.W. of it. The place contains 5454, and the canton 12,290 inhabitants, on a territory of 80 kiliometres, in 8 communes. The harbour can receive only about 60 ſmall veſſels. The town is ſeated on a ſharp rock, forming a peninſula of an oval form, and ſurrounded with walls; it has two gates, and two fauxbourgs. Near it is an oyſter-fiſhery, and on the land ſide quarries of large and very hard ſtones. N. lat. 48° 50'. W. long. 1° 32'.

GRANDVILLIERS, a town of France, in the department of the Oiſe, and chief place of a canton, in the diſtrict of Beauvais; 14 miles N.N.W. of Beauvais. The place contains 1633, and the canton 12,655 inhabitants, on a territory of 167½ kiliometres, in 22 communes. N. lat. 49° 39'. E. long. 2° 2'.

GRANDWALDEN, or Gran, a town of Norway, in the dioceſe of Chriſtiania; 26 miles S. of Chriſtiania. The town ſtands on an eminence in the midſt of an extenſive plain, looking down on ſeveral conical rocks, covered with firs, and remarkable for two churches in the ſame churchyard, called the "Two Siſters."

GRANGE, an ancient term for a barn, or place wherein to lay up and threſh corn.

The word is formed of the Latin *granea;* or of *granum, grain, corn*, &c. Hence alſo *granger* or *grangier,* a grange-keeper or farmer.

Hence *grange* is a name which was formerly much applied to ſuch farm-houſes as were provided with large barns, granaries, and other ſimilar offices, for the preſervation of grain, &c.

Grange is alſo uſed, in a more extenſive ſenſe, for a whole farm, with all the appendages of ſtabling for horſes, ſtalls for cattle, &c. and for an inn.

Grange, Joseph de Chancel de la, in *Biography*, born in 1676 of an ancient French family, at Antoniat in Perigord, exhibited from his boyiſh days a ſingular paſſion for poetry and romance. He was educated among the Jeſuits at Bourdeaux, and when he was only nine years old, he compoſed a comedy in three acts, which was repreſented by his ſchool-fellows. His early talents ſeemed to have marked him out for diſtinction, and his mother took him to Paris, and obtained for him the place of page to the princeſs of Conti. Before he was ſixteen, his tragedy of Jugurtha was repreſented in the capital, and was applauded as a moſt extraordinary effort of ſuch a ſtripling. He continued to write pieces for the ſtage, which were productive of reputation and pecuniary advantages; but the work which rendered him famous, though it expoſed him to much mortification and ſuffering, was entitled "Philippiques," a ſatire in verſe, directed againſt Philip, the regent duke of Orleans. This appeared in 1718, and it charged the duke with the crime of poiſoning ſeveral branches of the royal family.

The author attempted to eſcape, but, falling into the hands of his purſuers, he was committed to the priſon of St Marguerite. It appears that he was not brought to trial, and that he contrived to effect an eſcape from priſon and the country, but upon the death of the regent he returned to France, where he lived unmoleſted. He died at his family ſeat of Antoniat in 1758. His works were collected in five vols. 12mo. and, with his own corrections, publiſhed the year after his deceaſe. They conſiſt chiefly of tragedies, operas, and miſcellaneous poems. The tragedies are moſt eſteemed: they are ſaid to be "artful in the contexture of the plot, and abounding in intereſting ſituations, but feebly written, and trite in language and ſentiment." In his latter years he employed his time on a hiſtory of Portugal. In manners he had all the fire and vanity of a Gaſcon: he had few friends, and ſeems to have been more feared on account of his ſatirical powers, than beloved for his virtues.

Grange, in *Geography*, a town of Sweden, in the province of Dalecarlia; 33 miles S.S.W. of Falun.

Grange, *La*, a cape on the N. coaſt of the iſland of Hiſpaniola. N. lat. 19° 55′. W. long. 72° 30′. This cape, with Point de Dunes, forms the mouth of the bay of Monte Chriſti, in the county of Stirling.

Grange *Point*, a cape on the S. coaſt of the Iſle of Wight. N. lat. 50° 38′. W. long. 1° 15′.

Grange *River*, a river of Upper Canada, which empties itſelf into a bay of the ſame name on the N. ſhore of lake Superior, W. of the Cris. This river leads to Nipigan, a place which formerly furniſhed the beſt beaver and martin, and was the fartheſt advanced poſt of the French traders, at the time when Great Britain conquered Canada.

GRANGEA, in *Botany*, Adanſon, v. 2. 121. Juſſ. 184. Claſs and order, *Syngeneſia Polygamia-ſuperflua.* Nat. Ord. *Compoſitæ diſcoideæ*, Linn. *Corymbiferæ*, Juſſ.

Gen. Ch. *Common calyx* imbricated, ſpreading; its ſcales oblong, obtuſe. *Cor.* compound; the united florets of the diſk very numerous, tubular, five-cleft, regular; females fewer, in the circumference, tubular, three-cleft. *Stam.* in the united florets, filaments five, capillary, very ſhort; anthers united into a cylinder, with five teeth. *Piſt.* Germen ſmall; ſtyle thread-ſhaped, the length of the ſtamens; ſtigma undivided in the united florets, cloven in the female ones. *Peric.* none, except the permanent calyx. *Seed* ſolitary to both kinds of florets, obovate, compreſſed, crowned with a toothed border. *Recept.* hemiſpherical, naked.

Eſſ. Ch. Receptacle hemiſpherical, naked. Seed-crown membranous, toothed. Calyx imbricated, ſpreading. Florets of the radius three-cleft.

We have alluded to this genus under Ethulia, from which it differs in having a crown to the ſeed, florets of the radius three-cleft, and ſcales of the calyx obtuſe. It moſt approaches *Tanacetum* in character, but is ſufficiently diſtinct. The following are the only ſpecies we have been able certainly to determine.

1. G. *maderaſpatana*, (Artemiſia maderaſpatana; Linn. Sp. Pl. 1190. Tanacetum Ægyptiacum; Jacq Hort. Vind. v. 3. 46. t. 88. Abſinthium maderaſpatanum, ſenecionis incani folio, corymbis ſolitariis in ramulorum faſtigio ſpecioſis; Pluk. Amalth. 3. t. 353. f. 3. A. minus odoratum gangeticum, floribus chamæmeli ſolitariis e foliorum alis; Pluk. Almag. 2. Phyt. t 1. f. 2.)—Leaves ſinuated, ſomewhat lyrate, hairy. Flower-ſtalks elongated.—Native of the Eaſt Indies. *Root* annual, tapering, branched. *Stems* procumbent, a ſpan or more in length, ſubdivided, leafy, downy. *Leaves* alternate, ſeſſile, deeply pinnatifid, in a lyrate form, and ſinuated, clothed with ſoft whitiſh hairs, their ſegments rather rounded. *Flowers* yellow, almoſt globular, near half an inch in diameter, on axillary, ſolitary, ſimple, hairy ſtalks, half as long as the leaves. Linnæus in both editions of Sp. Pl. quotes Plukenet, t. 357. f. 3. Adanſon, his profeſſed critic, ſeems to have augmented the error in copying him, and cites t. 257. f. 3; which has given us a great deal of trouble; more eſpecially as we have a plant from the Paris garden for Adanſon's *Grangea*, which proves *Hippia integrifolia*, Linn. Suppl 389, and does not anſwer to the character or habit of *Grangea.* Nevertheleſs, as it came with ſuch authority, we have laboured in vain to find any thing like it in Plukenet, and thought for a while we had found it in t. 45 f. 3, which bears a rude reſemblance to our ſpecimen, but is *Parthenium Hyſterophorus.* Finally, Burmann's *Sphæranthus africanus*, Fl. Ind. t. 60. f. 2, which is not that of Linnæus, and which Juſſieu ſuſpects may be a *Grangea*, is not unlike this *Hippia.* If it be our plant, his ſuſpicion is refuted. The *leaves* in our ſpecimens are occaſionally undivided or lyrate, more cut than in Burmann's plate, and leſs ſo than in Plukenet's t. 45. f. 3. The calyx, however, which is well expreſſed in the latter for the *Parthenium*, does not accord with our's.

2. G. *minima.* (Artemiſia minima; Linn. Sp. Pl. 1190. Burm. Ind. 177. t. 58. f. 3.)—Leaves wedge-ſhaped, bluntly toothed, ſmooth. Flowers nearly ſeſſile.—Native of China, and the Eaſt Indies. We received it in 1803, from the ſtove of the late right honourable Charles Greville at Paddington, where it was preſerved rather for its rarity and ſingularity than beauty. It is an annual plant, much ſmaller in all its parts than the foregoing, ſmooth, proſtrate, of a light green colour. *Flowers* the ſize of a ſmall pea, axillary, nearly ſeſſile, whitiſh, ſometimes with a purple tinge. Their ſtructure is extremely minute.

We ſcruple to admit *Ethulia divaricata* into this genus, though ſomewhat ſimilar in habit, becauſe of its naked ſeed, and ſharp calyx. See Ethulia.

GRANGEMOUTH, in *Geography*, a village of Scotland, of conſiderable extent, founded by ſir Lawrence Dundas, upon the angle formed by the junction of the river Carron and the canal. It deſerves mention as a place of conſiderable trade. Veſſels bring into this port timber, hemp, flax, deals, and iron, from the Baltic, Norway, and Sweden, and grain from foreign markets, as well as from the coaſts of England and Scotland. The trade to London is carried on by the Carron ſhipping company; 3 miles E.N.E. of Falkirk.

GRANGERIA, in *Botany*, ſo named by Commerſon in memory of M. Granger, a ſurgeon, who travelled into Egypt and Judea between the years 1730 and 1736, from whence he ſent numerous ſeeds to enrich the botanic garden at Paris. He publiſhed, in 1745, in 12mo, *Relation du voyage fait en Egypte en* 1730, according to Haller, who mentions him as "not a trifling man, though he touched but ſlightly upon botany. He greatly depreciates the wonders and fertility of Egypt."—Juſſ. 340. Lamarck. Illuſtr. t. 427. Claſs and order, *Icoſandria Monogynia.* Nat. Ord. *Pomaceæ*, Linn. *Roſaceæ*, Juſſ.

Gen Ch. *Cal.* Perianth inferior, of one leaf, bell-ſhaped, with five ovate, acute, permanent ſegments. *Cor.* Petals five, roundiſh, ſcarcely longer than the calyx, inſerted into its rim. *Stam.* Filaments fifteen, awl-ſhaped, longer than the petals, inſerted into the calyx; anthers roundiſh. *Piſt.* Germen ſuperior, obovate, wooly; ſtyle one, thread-ſhaped; ſtigma obtuſe. *Peric.* Drupa obtuſe, ſomewhat triangular. *Seed.* Nut triangular, of one cell.

Eſſ. Ch. Calyx five cleft, inferior. Petals five. Germen woolly. Drupa with a triangular nut.

1. G. *buxifolia.*—A tree, native of the Iſle de Bourbon,

where it is called *Arbre de buis*, or Box tree, from the ſimilitude of its *leaves* to the *Buxus*. Theſe are about an inch long, ovate, acute, entire, veiny, ſmooth on both ſides, nearly ſeſſile, with a pair of ſmall awl-ſhaped *ſtipulas*. *Flowers* ſmall, in terminal or axillary cluſters. *Fruit* ſomewhat like that of an olive, but ſmaller, and rather angular.

GRANHULT, a town of Sweden, in the province of Smaland; 35 miles N. W. of Calmar.

GRANI, in our *Ancient Writers*, muſtachoes or whiſkers of a beard.

The word ſeems formed from the ancient Britiſh or Iriſh, *greann, a beard*.

It is given for a reaſon why the cup is refuſed to the laity, "Quia barbati, & prolixos habent granos, dum poculum inter epulas ſumunt, prius liquore pilos inficiunt, quam ori infundunt."

GRANIFEROUS, producing or bearing any ſort of grain.

GRANIFEROUS *Pods*, a term ſignifying ſuch pods as contain ſmall ſeeds of ſome of the grain kinds.

GRANILITE. Under this denomination Kirwan comprehends all varieties of granite that contain more than three ingredients, ſuch as quartz, feldſpar, mica, and garnet: ſuch ſupernumerary ingredients, however, muſt be conſidered as accidental, and of too little importance to confer the diſtinction of a particular name on the granite in which they occur.

GRANINGE, in *Geography*, a town of Sweden, in Angermannland, on a lake; 40 miles N. W. of Hernoſand.

GRANITE, an aggregate rock, the eſſential ingredients of which are feldſpar, quartz, and mica, being the ſame as thoſe of gneiſs, from which granite differs chiefly in the arrangement of the three component parts: their being mingled without order or regularity, produces a granular ſtructure, while that of gneiſs is generally ſlaty. (See GNEISS.) It is, probably, this granular nature of the rock in queſtion which has procured it its name; though ſome authors are of opinion that the word *granite* is nothing but a corruption of *geranites*, a name mentioned by Pliny, as that of a ſtone of the colour of a ſtork's neck. The fact is, that the word granite, which is now adopted by almoſt all European nations, originated with Italian antiquaries, and Tournefort was not the firſt writer who makes mention of it.

The three conſtituent parts of granite vary with regard to their colour, ſize, relative quantity, form, and freſhneſs.

The *colour* of this rock is generally more or leſs reddiſh, becauſe the feldſpar, uſually the predominating part, is oftener of that than of any other colour. Sometimes the feldſpar is greyiſh and yellowiſh-white, and ſo like the admixed quartz, that it can be diſtinguiſhed only by its peculiar fracture and luſtre. It has been obſerved that the red colour occurs more frequently in the newer, while the greyiſh-white appears to be more characteriſtic of the older formation of granite. Alſo long continued expoſition of granite to the action of the atmoſphere contributes to render its feldſpath pale or grey. Yellow and green feldſpar ſeldom occur as ingredients of granite.—The colour of the quartz is uſually greyiſh; ſometimes this part is perfectly colourleſs and tranſparent, in which caſe, as the grains cannot be viewed by tranſmitted light, it appears deep grey or black.—The mica is much more frequently black or grey, than brown or perfectly white.

The abſolute *ſize* of the ingredients of granite is ſubject to conſiderable variation; they are ſeen from very large to very fine granular, the latter being more frequent in the newer formation. With regard to the relative ſize of its conſtituent parts, we diſtinguiſh equally mixed from unequally mixed granite; the former being that in which the magnitude of the three ingredients is nearly the ſame.

The *quantity* of theſe parts is equally various: ſo that ſometimes one, ſometimes two of them predominate: upon the whole it is the feldſpar that is found in the greateſt proportion, and the mica in the leaſt. There are, indeed, ſome varieties of granite in which the quartz or mica are entirely wanting. Such binary aggregations of the granitic kind have received diſtinct appellations by ſome authors. Thoſe of quartz and feldſpar, or feldſpar and mica, were called ſimple granites by Wallerius; ſemi-granites by Blumenbach; and Kirwan propoſes to denote all theſe duplicates in general by the name *granitell*, ſpecifying, when neceſſary, the conſtituent peculiar parts of each. The aggregate of quartz and mica is called *geſtell-ſtein*, or *ſtell-ſtein*, by ſome of the older German writers; and that of feldſpar and mica, eſpecially when the latter is of a brown or browniſh-red colour, and forms the predominant ingredient, has obtained the Finlandic name of *Rapakivi*. Such dictinctions, however, are unneceſſary and inapplicable, ſince often in one and the ſame granitic maſs the proportion and number of the component parts are ſeen conſiderably to vary. Beſides, there are many rocks enumerated by authors as granitels, which cannot, with any propriety, be referred to granitic compounds; ſuch as feldſpar with hornblende, with nephritic ſtone, with garnet, ſteatite, or the ſame ſeparately combined with quartz or mica.

There is but very little variety in the *form* of the component parts: they are almoſt always maſſive and indeterminately angular, and ſeldom occur in the form of regular cryſtals. The feldſpar is found cryſtallized in Bohemia, at Schlakkenwalde, near Carlſbad; at Tzeidler, in the Saatz diſtrict; alſo near Hohenwalde, in Upper Palatinate; at Ochſenkopf and Keſſein, on the Fichtel-gebirge; at Schneeberg, in Saxony; in England; in the iſland of Arran, &c. The granite in which theſe feldſpar cryſtals are ſeen, is often of ſuch fine grain, and the quartz and the mica are ſo intimately united with each other, that they form, as it were, a matrix for the cryſtals: ſuch granite is called *porphyritic* granite. Part of the pavement on Weſtminſter and Blackfriars' bridge conſiſts of this ſpecies of granite. Something like cryſtallization of the quartz is now and then obſerved in granite, but it is always irregular. In the variety, called graphic or Portſoy granite, in which the feldſpar conſtitutes by far the greateſt part of the maſs, and which contains mica in ſmall groups, at great diſtances from each other, the quartz is diſpoſed in ſuch a manner, that when the rock is cut in a certain direction, it exhibits forms which bear ſome diſtant reſemblance to written characters: whence it has obtained its name. But by ſome, neither the Portſoy nor Siberian graphic ſtones are conſidered as true granites.—Alſo, the mica is now and then found cryſtallized in granite, ſuch as in Siberia, at Waldheim, Metweida, Johan-georgenſtadt, in Bohemia, &c. In a variety of granite of Mount St. Gothard, all the three conſtituent parts are ſaid to occur cryſtallized together.

The feldſpar is alſo ſometimes found in the ſhape of cuneiform concretions, repreſenting on their fracture a ſurface comparable to the paws of ſome animals, or to the petals of flowers: this ſingular variety comes from the neighbourhood of Breitenbrunn, in the Upper Ertzgebirge.

With regard to the *freſhneſs* or ſtate of preſervation which theſe three ingredients exhibit, we have to obſerve that the feldſpar, which, in general, has a vitreous luſtre and a perfectly foliated fracture, is alſo ſeen in various ſtages of decompoſition; it occurs dull, earthy, friable, and even entirely diſintegrated, in which ſtate it is known by the name of porcelain-earth. This diſintegration takes place chiefly near the ſurface of granitic mountains, and in the immediate vicinity of veins. Granite, with feldſpar thus converted into an earthy ſtate, is found in Cornwall, on the Hartz, at Burkardſgrün in Saxony, &c.; and it is probable to Mr. Emmerling that the gieſs-ſtein, (Saxum fuſorium, Linn.) which, on account of its looſe texture, is made uſe of in the braſs founderies of Sweden and France, may be granite in a ſimilar ſtate of incipient decompoſition. Alſo, the mica is ſubject to diſintegration, eſpecially when acted upon by ſubterraneous water and vapours; the maſs into which it is thus converted is conſidered as being of the nature of ſteatite. In this ſtate it is found at Fichtelberg, in the Upper Palatinate, and in the vicinity of Tornitz, near Carlſbad, in Bohemia.

Beſides feldſpar, quartz, and mica, other foſſils are found admixed, which, not being conſidered as eſſential, are generally diſtinguiſhed by the appellation of *accidental ingredients*. They are, 1. Shorl; the moſt frequent of all. It occurs maſſive and diſſeminated, ſometimes alſo cryſtallized, and appears principally to belong to the old granite-formation: it is found in ſeveral parts of Saxony, in Lower Bavaria, Upper-Palatinate, Wirtenberg, Tranſylvania, Cornwall, &c.; 2. Garnet: moſtly in ſmall grains. It occurs but rarely; but has been found near Leipzig (in boulders), at the Greifenſtein, and in the neighbourhood of Voigtsdorf, in the vicinity of Freiberg, in Saxony, in Lower Bavaria, &c. An aggregate of quartz, mica, and garnets, is by the Swedes called norka or murkſten. 3. Tinſtone; frequent in the granite of Geier, Zinnwald, &c. 4. Nephrit or jade appears to occur not only in gneiſs, but alſo with real granite, in Switzerland. 5. Rock cryſtal. 6. Beryl; in the iſland of Alba, and perhaps alſo in Siberia. 7. White common opal, ſometimes occurs in the granite of Eibenſtock in Saxony. 8. Topaze is ſometimes ſeen, together with tinſtone, in the granite of Zinnwald. 9. Calcareous ſpar, very ſeldom. 10. Fluor-ſpar, the ſame; in Siberia, at Geier in Saxony. 11. Barytes, equally ſeldom; in Switzerland.

Foreign beds are leſs frequently met with in granite than in other rocks. The more remarkable ones are thoſe of tin-ſtone, galena, and blende at Zinnwald on the Bohemian frontiers; the beds of mica, particularly in Sileſia and Luſatia; of quartz, and rock cryſtal in Switzerland. Alſo beds of feldſpar are ſaid to occur in it. The green feldſpar, called Amazon ſtone, is found in large maſſes in the granite of the Ural mountains of Siberia.

Stratification of Granite.—Though granite occurs frequently as widely-extended maſſes, in which the eye is unable to diſcover any continued traces of parallel ſeparation; yet there can be no longer any doubt that thoſe geologiſts, who abſolutely denied the exiſtence of ſtratified granite, were either entirely unacquainted with the ſtructure of many of the European granitic mountains, or too much influenced by the principles of their favourite theories, to allow the obſerved traces of demarcation to be any thing but irregular and accidental rents and fiſſures. Pini even endeavours, by mathematical figures, to prove the impoſſibility of ſtratification in granite. Notwithſtanding all this, the obſervations of the moſt eminent geologiſts appear to prove that ſuch ſtratification, even in the ſtricteſt ſenſe of the word, is not uncommon; but it is often a matter of great difficulty, for an eye, unaccuſtomed to viewing the ſtructure of mountains on a large ſcale, to diſtinguiſh the paralleliſm, or to follow the obſcurely marked progreſs of the line of ſeparation of the ſtrata, eſpecially when they are of conſiderable thickneſs.

But in many caſes, it would appear that this ſtratification is too diſtinct to leave any doubt upon the mind of the obſerver. Nothing can be more convincing than the account given by Gruber of the ſtratified nature of the granite compoſing the Rieſengebirge, that ſeparates Sileſia from Bohemia. The rocks that chiefly compoſe this celebrated range of mountains are granite and gneiſs, which, on the higheſt points, ſuch as the Rieſen and Schnee-kuppe, are ſeen in fourfold alternation. Mr. Gruber has aſcertained the dip and direction of the ſtrata in eight places, and proved them to be perfectly diſtinct from the rents which are frequently ſeen nearly at right angles with the lines of ſtratification.

From Sauſſure's obſervations, made on the ſeveral granitical pyramids or "aiguilles" of the Mont-Blanc, it would appear that all the parts of this mountain are compoſed of vaſt layers of granite perpendicular to the horizon, and directed from N.E. to S.E. Still more diſtinct this ſtratification appears on Mount St. Gothard. (See GOTHARD.) According to Charpentier, Leſke, and others, alſo the granite of the whole of Upper Luſatia, and of ſeveral parts of Saxony, affects the ſtratified ſtructure.

In a ſimilar manner Mr. Gruber obſerved the regular ſtratification near Carlſbad and Teplitz; and Dr. Reuſs found the ſame in ſeveral other parts of Bohemia; ſuch as in the Eger diſtrict, where the ſtrata dipped north at an angle of 18°; in the Saatz diſtrict at Leſchkau; in the Leutmeritz diſtrict on the Saxon frontiers; at the Wolfsberg, where the ſtrata run from two to ſix feet in thickneſs; as alſo in ſeveral places in the diſtrict of Buntzlau, towards the Rieſengebirge. La Perouſe deſcribes the granite of part of the Pyrenees as diſpoſed in layers or beds.

In the north of Europe, ſimilar regularity appears to prevail in the ſtratification of granite; thus, according to Cronſtedt and others, in Sweden, on the Kinnekulle and Billing, in Weſt Gothland, the granite (conſiſting moſtly of red feldſpar, white quartz, and black and greeniſh mica, in nearly equal proportion) is obſerved in diſtinct layers, with ſuperincumbent ſtrata of rocks of ſubſequent formation.

Pallas followed vaſt and continuous layers of granite through whole tracts of mountains in Siberia: indeed, part of the granitic Ural mountains, in the neighbourhood of the lake Kolywan, are deſcribed as having the appearance of huge artificial ſtructures, in which the layers appear to be looſely piled on one another.

Dr. Hutton ſuppoſed granite, when not ſhiſtoſe in its ſtructure, to be altogether unſtratified; profeſſor Playfair, however, in his expoſition of the Plutonic ſyſtem, ſo far differs from the opinion of his ingenious friend, that he allows granite to form ſtrata alſo where it has no character of gneiſs; and he thinks that this admiſſion does not embarraſs the theory with any new difficulty; but, on the other hand, he ſuſpects that the ſtratification aſcribed by the Neptuniſts to the granite mountains is, in many inſtances, either an illuſion, or at leaſt ſomething very different from what, in other ſtones, is accounted ſtratification. Profeſſor Playfair found ſtratified granite, in England, at Chorley Foreſt, in Leiceſterſhire, where, particularly near Mount Sorrel, beds of granite are ſeen, holding the ſame direction with thoſe of the ſubjacent "horn-ſtone ſchiſtus;" and likewiſe at Faſſnet-water in Berwickſhire, where the beds of granite run from about S.S.W. to N.N.E. conformable to the ſchiſtus on either ſide of them. Reſpecting the granite mountains of Arran, we have it obſerved by the ſame philoſopher that this ſtratification appears doubtful. The mountain of Goatfield, in that intereſting iſland, appeared, contrary to what Mr. Jameſon had advanced in his "Mineralogy of the Scottiſh Iſles," without any veſtige of ſtratification in its granitic part, as did alſo the whole group of mountains to which it belongs; for though he ſaw large tabular maſſes, ſometimes nearly vertical, ſeparated by fiſſures, they appeared to him to be much too irregular, too little extended in length and height, and vaſtly too much in thickneſs, to be reckoned the effects of ſtratification. As in the third volume of Jameſon's "Syſtem of Mineralogy," Arran is not mentioned among the localities where ſtratified granite occurs, it would appear as if that geognoſian does not lay any ſtreſs upon his firſt remark on the nature of the above-mentioned mountain.

The relative age of the different varieties of granite has engaged the attention of ſeveral writers on geology; but it muſt be ſaid, that moſt of the opinions that have been broached on this ſubject, and the various ideas entertained by theoriſts reſpecting what they call regeneration of granite, are too vague, or at leaſt too little founded on actual obſervation, to be entitled to particular notice. Some geologiſts on the other hand have abſolutely denied the exiſtence of a ſecond and third granite-formation. The Wernerian ſchool admits three diſtinct formations of granite. The *firſt* or *oldeſt* is that which, of all rocks we are acquainted with, is ſunk the deepeſt into the interior of the earth, and which therefore may with propriety be conſidered as the fundamental rock. This oldeſt granite alſo conſtitutes the higheſt parts of the ſurface of the earth, and, thus elevated, is generally ſurrounded, and, as it were, enveloped by other primitive rocks. It is frequently coarſe-grained and porphyritic. It occurs both ſtratified and unſtratified; and it is the latter which is often ſeen in large globular diſtinct concretions of conſiderable dimenſions, ſuch as in ſeveral parts of Bohemia, in the Fichtelgebirge, in the iſland of Arran, &c.

This formation is, of courſe, far more widely extended than thoſe of a more recent origin. The *ſecond granite formation* is conſidered as occurring only in veins which never reach any of the newer rocks, but are confined to the oldeſt formation. Such granite is marked with leſs regularity of ſtructure, than what is obſerved in the older formation; at the ſame time that it ſurpaſſes the neweſt granite, both with regard to the regularity of arrangement, and ſuperior firmneſs of the conſtituent parts. The *third*, or *neweſt granite-formation*, is always found ſuper-incumbent on older primitive rocks, often in an unconformable and over-lying poſition: it alſo occurs in veins, which have been ſeen to interſect or traverſe veins of the ſecond granite formation; as a certain criterion of the greater relative age of the latter. Its ſtructure, according to the characteriſtic given of it by profeſſor Jameſon, is very irregular; it has a deep red colour, and contains ſometimes grains of garnet, and often fragments of various primitive rocks of various magnitude. When it occurs in veins, theſe are, according to the ſame author, not connected with any rock beyond the ſtrata which they traverſe. Examples of this neweſt formation are, that at Greifenſtein, a large group of ſteep rocks between Ehrenfriederſdorf and Geier in the Saxon metalliferous mountains, where the coarſe granular and irregularly aggregated granite, compoſed principally of feldſpar and quartz, with but a ſmall portion of mica, occurs reſting on mica ſlate, in an unconformable and over-lying poſition: it contains neſts of quartz and feldſpar, as alſo fragments of gneiſs and mica ſlate, from the ſize of a cubic each, to that of 100 cubic feet and upwards Another inſtance of this formation we have in the tin ſtockwork at Geyer, where it is contained in a hollow of gneiſs, and agrees in its characters with that of Greifenſtein. Another portion of the ſame formation, is that at Johanngeorgenſtadt, Auerſberg, and Eibenſtock, where, however, it occurs only in veins, which are from a foot to ſeveral fathoms wide, and are uſually traverſed by metalliferous and other veins. Mr. Mohs has given a very good characteriſtic of this newer granite. Veins of the ſame kind occur alſo in Bohemia, Upper Luſatia, at Miſella in the Alps, in the Shetland iſlands, in Glen Moriſon, and in the Highlands.

The nature of the juſt mentioned *granitic veins* is conſidered in a different light by Dr. Hutton, according to whom all veins, whether they are obviouſly connected, or whether they have no apparent connection, with any large maſs of granite, are coeval with, and conſtitute a part of the main body of what is called the oldeſt granite by the followers of the Neptunian ſyſtem. Mr. Playfair has given ſeveral examples of veins inviſibly connected with larger maſſes; in thoſe at the iſle of Coll, in the Hebrides, at Portſoy, in Cornwall, in Glen Tilt; and of ſuch as are viſibly connected with the main granitic body, in thoſe occurring in the iſland of Arran, in Galloway, in Inverneſs-ſhire, St. Michael's Mount, Cornwall. Mr. Jameſon, however, ſays that he has convinced himſelf, after a very careful examination of the rocks of the iſland of Arran and of Galloway, that they do not afford a ſingle inſtance of granite veins, ſhooting from the oldeſt granite into the adjacent rocks, nor of veins traverſing newer primitive rocks, as it has been inſinuated to be the caſe with the granite veins in Glen Tilt. The ſame author obſerves on this occaſion, that veins of feldſpar have been frequently confounded with granite veins, and he ſubjoins ſome obſervations on this ſubject communicated by the late Dr. Mitchell, according to which there is a moſt palpable difference between ſuppoſed and genuine granite veins; the former being frequently narrower than one inch, and commonly much ramified, and ſometimes tortuous; but they conſtantly adhere moſt firmly to the adjacent ſtone, and when they contain apparent fragments, the ſlaty ſtructure of theſe is ever conformable to that of the contiguous rock; while genuine granite veins never fall ſhort of ſome inches, are always pretty ſtraight, ſeldom giving off branches: they have a diſtinct ſeparation, and contain fragments of the adjacent rock, which lie promiſcuouſly; the granite is conſtantly uniform, containing the three ingredients equally mixed; and Dr. Mitchell has always found it ſmall-grained. The ſuppoſed granite, according to him, conſiſts of feldſpar, of a very unequal grain, incloſing ſometimes ſpots of mica, and rarely ſpecks of quartz. From all which this mineralogiſt concludes, that the laſt mentioned veins are nearly of contemporaneous origin with the rocks in which they are contained, and ought, therefore, to be conſidared as, and called, feldſpar veins.

Although granite is the hardeſt, and one of the moſt durable rocks we are acquainted with, it is, nevertheleſs, ſubject to *diſintegration*, which manifeſts itſelf not only in the crumbling of the ſurface of the expoſed parts of granitic beds, but likewiſe in the ſeparation of vaſt maſſes, which, being diſunited by the enlargement of the rents and fiſſures that generally traverſe the granitic mountains, or croſs the ſtrata in a nearly vertical direction, are partly precipitated from their high ſituation, partly diſplaced in various manners, ſo as to produce the appearance of huge artificial ſtructures, and of other objects to which the fancy of the beholder may compare them.

M. De Luc has ſeen on the Rieſenbirge, in Sileſia, a number of pillars produced by ſuch diſintegration, both ſolitary and grouped together, in a ſtraight line, and, at a diſtance, preſenting the appearance of many high piles of gourds.

The Adon-ſholo mountains in Dauria, which conſiſt of granite, are, according to Pallas, in many parts broken into all manner of ſhapes, repreſenting vaſt ruins, grottos, and immenſe flat maſſes piled on one another in all directions.

—Several of the mountains are, as it were, ſtrewed with blocks of granite, which, at a diſtance, appear as numerous herds of cattle; and it is this circumſtance which is ſaid to have procured this ridge the name of Adon-ſholo, a Mongole word, denoting herd-like mountains. All theſe detached rocks are fragments of the vaſt ſtrata of granite that compoſe the greateſt part of the Dauric mountains. The ſummits of the Goatfield and other mountains of Arran have the appearance of huge walls compoſed of large granitic maſſes. At Huelgouet, in Lower Brittany, we are informed by Monnet, as alſo in the Voſges, enormous maſſes of granite are ſeen piled on one another, and forming moſt extraordinary groups. The granite being here divided into maſſes by fiſſures, which are filled up with granite poſſeſſing leſs ſolidity, this latter is ſooner acted upon by atmoſpheric agency, whence, by its diſintegration, the maſſes become perfectly detached, and adopt various poſitions. But beſides the accidental groups formed by the rolling down of the rocks, there are other groups of granitic rocks at Huelgouet, that appear to be in their natural poſition, and many of them form an aſſemblage of rock maſſes, which have a perfectly rhomboidal form, and are regularly joined to each other by means of their correſponding planes. One of the inſulated rocks in a group at Huelgouet, is called *Pierre branlante*, or the rocking ſtone: it is 21 feet long, ſeven feet high, and eight feet wide, and its cubical content is 1160 feet: it is ſo accurately poiſed on the edge of another rock, which ſerves for its baſe, that the ſtrength of a few men ſuffices to change its centre of gravity, and to communicate an oſcillatory motion to it. The phenomenon of the *rocking ſtones* is not unknown in this country; the largeſt is that ſeen at the Land's End in Cornwall, where they are called Logan-ſtones; it weighs upwards of ſixty tons, reſting on another rock of granite of conſiderable height cloſe on the ſea-ſhore. "The two ſtones," ſays Mr. Playfair, who avails himſelf of this phenomenon among others to explain the migration of ſtony maſſes, "touch but in a ſmall ſpot, their ſurfaces being conſiderably convex towards one another. The uppermoſt is ſo nearly in an equilibrium, that it can be made to vibrate by the ſtrength of a man, though to overſet it entirely would require a vaſt force. This ariſes from the centre of gravity of the ſtone being ſomewhat lower than the centre of curvature of that part of it on which it has a tendency to roll; the conſequence of which is, that any motion impreſſed on the ſtone forces its centre of gravity to riſe, (though not very conſiderably,) by which means it returns whenever the force is removed, and vibrates backward and forward, till it is reduced to reſt. Were it required to remove the ſtone from its place, it might be moſt eaſily done, by cutting off a part or blowing it away by gun-powder; the ſtone would then loſe its balance, would tumble from its pedeſtal, and might roll to a conſiderable diſtance. Now, what art is here ſuppoſed to perform, nature herſelf in time will probably effect. If the waſte on one ſide of this great maſs ſhall exceed that on the oppoſite in more than a certain proportion, and it is not likely that that proportion will be always maintained, the equilibrium of the Logan-ſtone will be ſubverted, never to return. Thus we perceive how motion may be produced by the combined action of the decompoſition and gravitation of large maſſes of rock."

It was probably from ſeeing the fantaſtical and imitative forms produced by granitic cliffs, and by the diſintegration of granite, that M. Vitte framed his unfortunate hypotheſis reſpecting the pyramids of Egypt, and the ruins of Perſepolis, Palmyra, and Balbec, all which, together with the temple of Jupiter at Girgentum, the palaces of the Incas in Peru, &c. &c. were conſidered by that antiquary as productions of nature.

Granite is much leſs *metalliferous* than gneiſs and other primitive mountains; but tin and iron abound in it. Beſides theſe, ſeveral other metals occur in it in ſmall proportion, *viz.* gold, though very rarely, in Peru; native ſilver, almoſt equally ſeldom, at Wittichen and Alt Wolfach, in the Black Foreſt, near veins of ſilver and cobalt; copper; galena, for inſtance, at Schreiberſhauſen, at the foot of the Schneekuppe, in Sileſia; biſmuth, zinc, cobalt, manganeſe, molybdena, arſenic, tungſtein, and wolfram, all which occur generally in ſmall veins; but tin, galena, and blende, are found in beds at Zinnwald in Saxony, and in Bohemia.

As to the *extent* of granite over the world, it may be ſaid that ſcarcely any country we are acquainted with is entirely deſtitute of that rock. In Aſia we have the Uralian and Altaic mountains, with the Caucaſus; in Africa, the Atlas, ſeveral mountains of Egypt, thoſe of the Cape of Good Hope; in North America, ſome mountains of New York, Pennſylvania, and Virginia; in South America, great part of the Andes, the mountains de los Mariches in the Carracas, the Cordilleras of Parima, Sierra Nevada de Merida, &c.; in Europe, the Seewoga mountains of Scandinavia, thoſe of Finnland, the Carpathes, the Hartz, the Rieſen-gebirge, the mountains of Upper Luſatia, a part of the Saxon metalliferous mountains, (eſpecially Eibenſtock, Johangeorgenſtadt, Schwartzenberg, Schneeberg, Ehrenfriederſdorf, Geier, Nauendorf, Altenberg, and Zinnwald,) the Fichtel-gebirge, the Odenwald and Schwartzwald, the Alps of Swiſſerland and Savoy, the Apennines, Pyrenees, the mountains of Cornwall, &c. all which have granite for their principal conſtituent rock.

The *uſe* made of granite is manifold; it is employed for building, paving, ſteps, for troughs in ſtamping mills, for millſtones, &c.

The uſe of granite for architectural and economical purpoſes is perhaps no where more amply diſplayed than at Peterſburg, where not only the imperial and other palaces, but even ordinary dwelling houſes, have their lower parts lined with ſlabs of granite. The left bank of the great Neva, from the foundery to the gulf of Cronſtadt, and both banks of the Fontanka and of the Catharine canal, are lined by high walls conſtructed of ſuch ſlabs of granite; as are many bridges over the Neva, baluſtrades, &c. The pillars, ſtairs, balconies, &c. in the palace of Cronſtadt, are almoſt all of the fineſt kinds of granite. Thoſe employed for ornamental architecture are cut and poliſhed by lapidaries; but thoſe intended for leſs delicate purpoſes, ſuch as common ſlabs, ſteps, cylinders, troughs, &c. are worked by peaſants, particularly by thoſe of Olonetſk. The government towns, however, Moſcow not excepted, are too diſtant from the chief granite mountains, to be enabled to make frequent uſe of that rock for the above purpoſes.

Granite has been more particularly applied, together with ſienite, for the purpoſes of architecture and ſtatuary, by the ancients, eſpecially by the Egyptians; and many very intereſting monuments of their ſkill and patience are ſtill exiſting in the collections of antiquities.

M. Brand has divided the different granites uſed in the arts after their predominant colours; the following are the principal varieties, in which, however, the black and white kind is not included, one of its ingredients being hornblende, which aſſigns it a place among the ſienites. See SIENITE.

Grey Granite of Cheſſi, in the department of the Rhine; it conſiſts of white quartz and black mica, with large cryſtals of roſe-coloured feldſpar. The columns of the Egliſe d'Enée (ancient temple of Auguſtus) at Lyons, are of this kind of granite, which has alſo been worked by the Romans.

Grey Granite of Thain.—It conſiſts of grey quartz, black mica, and white feldſpar cryſtals, which are ſometimes from two to three inches long. The quarries of this granite are on the road from Lyons to Valence, on the right bank of the Rhone. It is very well adapted for the conſtruction of large monuments. The granite of St. Peray, not far from Thain, is exactly like this, except that its feldſpar cryſtals are of a roſe-colour.

Grey Granite of Lavezzi.—Found in the ſmall iſland Lavezzi, near Bonifacio, S. of Corſica, in the ſtraits that ſeparate this iſland from Sardinia. This granite is compoſed chiefly of ſmall irregular cryſtals of feldſpar, mixed with a little black mica, beſides which it contains alſo feldſpar cryſtals, of a milk-white colour. In the quarry of that iſland a large unfiniſhed column is to be ſeen, which has been relinquiſhed by the Roman workmen.

Grey Granite of Elba.—Its grain is pretty uniform; its colour ſometimes approaches to light violet. There are four columns of this variety to be ſeen in the Muſée Napoleon: they were taken out of the church which contained the tomb of Charlemagne, at Aix-la-Chapelle.

The grey granites are much more common than the green or greeniſh, of which the following deſerve to be mentioned.

Antique green Granite.—Its predominant ingredient is white quartz, which contains here and there ſome light green feldſpar. There is a column of it in the Villa Pamfili, near Rome.

Fine grained antique Granite.—(Baſalte verd oriental.) The component parts of this work are ſo minute and intimately blended, that they can ſcarcely be diſtinguiſhed by the naked eye. Its colour approaches to deep olive. It is very hard, and takes a fine poliſh. The Egyptians have much employed it for the conſtruction of monuments; and ſeveral ſtatues of it may be ſeen in the Capitol and the Villa Albani. There is another variety with white ſpots, which is known at Rome under the name of Baſalto Orientale pidochioſo; this is very rare, for there are but two columns of it in exiſtence, namely, in the church of St. Pudentiana at Rome. Some varieties bearing that name are ſienite.

Granite of St. Chriſtoph:—compoſed of violet quartz, white feldſpar, and green mica. This magnificent rock is found at Oiſans, in the department of the Iſere.

Corſican orbicular Granite.—This beautiful rock (which probably belongs to the ſienite formation) was diſcovered by M. Barral, in the iſland from which it derives its name. Its compoſition is very extraordinary; it has a baſis of ordinary grey granite, which, however, in moſt parts, exhibits a conſiderable portion of hornblende. But what more particularly characterizes it, is a number of balls, of from one to two inches in diameter, each compoſed of ſeveral concentric and perfectly parallel layers, the outermoſt of which, generally white, opaque, and two or three lines thick, is compoſed of quartz and feldſpar, blended in various proportions, and exhibiting a radiated appearance, rather converging towards the centre of the ball. The ſecond layer, which is of a greeniſh-black colour, and about one line thick, is compoſed of fine laminar hornblende; and this is ſucceeded by a white, generally tranſlucid quartz layer, of about four or five lines in thickneſs, incluſive of two or three very thin layers of hornblende, that are generally ſeen within the ſubſtance of this third principal layer. Each of theſe layers is generally of equal thickneſs in the whole of its circumference. Theſe three parts may be conſidered as the coating: the interior of each ball is leſs defined than the ſurrounding layers; it conſiſts of a blackiſh and a whitiſh ſubſtance, the former ſurrounded by, and paſſing into the latter, the centre of which is uſually a dark-grey ſpot.

The quarry of this rock is unknown, a ſingle block only having been found in the gulf of Valinco, in Corſica: its weight was about 80 pounds; but it was ſoon broke into ſmall fragments, which are now diſtributed among collectors. There is a beautiful vaſe of it, one foot ſix inches high, in the cabinet of M. Dedree. The granite of Corſica is figured by M. Faujas de St. Fond, in his "Eſſai de Géologie," and in Mr. Sowerby's "Exotic Mineralogy."

Among the red granites, we have what is called *red oriental granite*, which, as uſually containing hornblende, often in large ſeparate patches, will be deſcribed under SIENITE.

The red Granite of Ingria.—This granite, ſays M. Patrin, is diſtinguiſhed from others in this, that the feldſpar, inſtead of being in grains, or parallelopiped cryſtals, as in moſt other granites, conſtantly appears in the ſhape of round or oval pieces of from half an inch to two inches in diameter. This granite takes a very fine poliſh, and in this ſtate exhibits the feldſpar in the ſhape of white, round, or oval *chatoyant* ſpots, in a reddiſh ground. The rock, which ſerves as a pedeſtal of the equeſtrian ſtatue of Peter the Great, at St. Peterſburg, is of this granite: the block was originally 32 feet long, 21 feet thick, and 17 feet long; but, in order to give it its preſent ſhape, imitative of a pictureſque natural rock, it has been much diminiſhed in ſize. This block was diſengaged from a ſwamp, about forty verſts from Peterſburgh: its weight was calculated to be above three millions of pounds. We have ſeen ſeveral fragments that were detached from the very block forming the pedeſtal of the ſtatue; but in none of them did we obſerve the form aſcribed by Patrin to the feldſpar.

The public ſummer promenade-garden at Peterſburg is decorated with a ſuperb colonade of this granite: the columns, which are ſixty in number, are of the Tuſcan order; their ſhafts, made of one piece, are about twenty feet high, and three feet in diameter. The iſland, called Kotlin-Oſtrow, on which is the fortreſs of Cronſtadt, is covered with blocks of this granite, the feldſpar of which is ſometimes of the kind called Labrador-ſtone.

Red Granite of the Voſges Mountains.—This granite is compoſed of large laminæ of roſe-coloured feldſpar, grey grains of quartz, and ſmall ſcales of mica. It has ſo ſtrong a reſemblance to the Egyptian red granite, that it is difficult to diſtinguiſh them. Its quarries are on the heights of Montaujeu, near the Papean mountains, in the Voſges.

Violet Granite of Elba.—The feldſpar of this variety is in large violent cryſtals. The pedeſtal of the equeſtrian ſtatue, in the Piazza della Santiſſima Annonziata at Florence, is made of it, as are alſo the ſodes in the chapel of St. Laurence in the ſame town.

Roſe-coloured Granite of Baveno.—This beautiful granite conſiſts of fleſh-coloured feldſpar, white quartz, and ſome grains of black mica. Conſiderable quarries of it are found on the borders of the Lago Maggiore, which are worked, without intermiſſion, for ſupplying Milan, and the whole of the neighbouring country, with this granite. It takes a very fine poliſh: here and there it exhibits ribbands, or zones, of a grey colour, which are compoſed of the ſame ingredients as the reſt of the maſs, but reduced into very minute particles. Many columns, porticos, &c. are ſeen of it at Milan.

The name of *graphic granite* is given to thoſe kinds in which the feldſpar forms large concretions, intermixed with grey quartz-cryſtals, exhibiting, when cut tranſverſely, angular figures, moſtly ſhaped like a 7; while others are leſs regular, and bear a diſtant reſemblance to rude alphabetical writing. They are not conſidered to be genuine granite by ſome mineralogiſts.

Graphic Granite of Portſoy.—The feldſpar is of various tints of pale fleſh-red; the quartz dark, but tranſparent, with now and then ſome ſmall particles of mica. This rock is minutely deſcribed by Dr. Hutton.

Graphic Granite of Siberia.—Its feldſpar is of a yellowiſh-white, or reddiſh colour; the quartz, exhibiting figures ſimilar to thoſe of the quartz in the preceding ſort, is of the variety called ſmoaky topaze. Mica occurs in it in ſmall neſts, and black ſhorl in acicular cryſtals.

Graphic Granite of Autun.—Of a pale roſe-colour; quartz-cryſtals grey, very numerous. It is found in the neighbourhood of Autun, department of Saône-et-Loire, particularly at Marmagne. This, in M. Brand's opinion, is the moſt beautiful of all graphic granites. Another variety of this ſtone is found at the ſame place: its feldſpar is white; the quartz grey, in ſmall cryſtals; it is ſuſceptible of very fine poliſh.

Graphic Granite of Corſica.—Likewiſe of a roſe-colour; but generally paler than that of Autun, from which it is alſo diſtinguiſhable, by its quartz-cryſtals being larger, and at greater diſtance from each other. It contains ſome thinly diſſeminated bronze-coloured mica. It takes a fine poliſh.

GRANIVOROUS, an epithet or denomination given to ſuch animals as feed upon corn, or any other grain or ſeeds.

Granivorous animals are chiefly of the bird kind. Theſe have a peculiar proviſion for the digeſting of ſo dry and hard a food.

GRANNA, in *Geography*, a town of Sweden, in the province of Smaland; 18 miles N.N.E. of Jonkioping.

GRANO, in *Biography*, a performer on the trumpet and German flute, and a compoſer of tunes for thoſe inſtruments, which had their day of favour in the early part of the laſt century. He was a kind of mungrel dilettante, who during many years condeſcended to make concerts and give leſſons, en profeſſeur, always inſinuating that it was merely for the pleaſure of amuſing the public and inſtructing individuals. Grano's trumpet march was long uſed by the Guards.

GRANON, in *Geography*, a ſmall iſland on the W. ſide of the gulf of Bothnia. N. lat. 61° 5′. E. long. 17° 5′.

GRANSEE, a town of the Middle Mark of Brandenburg; 30 miles N.N.W. of Berlin. N. lat. 52° 59′. E. long. 13° 13′.

GRANSO, an iſland in the Baltic, near the E. coaſt of Sweden. N. lat. 57° 46′. E. long. 16° 5′.

GRANSON, a town of Switzerland, in a bailliage of the ſame name, belonging to Bern and Friburg, ſituated between the lake of Neufchatel and mount Jura, and remarkable for the battle in which Charles the Bold, duke of Burgundy, was defeated by the Swiſs in 1476; 16 miles S.W. of Neufchatel. N. lat. 46° 50′. E. long. 6° 26′.

GRANT, Concessio, in *Law*, the regular method by the common law of transferring the property of *incorporeal* hereditaments, or ſuch things of which no livery can be had. (Co. Litt. 9.) For which reaſon all corporeal hereditaments, as lands and houſes, are ſaid to lie in livery; and the others, as advowſons, commons, rents, reverſions, &c. to lie *in grant*. (Ibid. 172.) The reaſon is thus given by Bracton (l. ii. c. 18.): "*traditio*, or livery, *nibil aliud eſt quam rei corporalis de perſona in perſonam, de manu in manum, tranſlatio aut in poſſeſſionem inductio; ſed res incorporales, quæ ſunt ipſum jus rei vel corpori inhærens, traditionem non patiuntur.*" Theſe, therefore, paſs merely by the delivery of the deed. And in ſigniories, or reverſions of lands, ſuch grant, together with the attornment of the tenant, (while attornments were requiſite,) were held to be of equal notoriety with, and therefore equivalent to, a feoffment and livery of lands in immediate poſſeſſion. It therefore differs but little from a feoffment, except in its ſubject-matter; for the operative words therein commonly uſed are "*dedi et conceſſi*," "have given and granted." For the difference between gifts and grants, ſee the article Gift. The king's grants are matter of public record. (See Record.) No freehold can be given to the king, nor derived from him, but by matter of record. To this end a variety of offices are erected, communicating in a regular ſubordination one with another, through which all the king's grants muſt paſs, and be tranſcribed, and enrolled; that the ſame may be narrowly inſpected by his officers, who will inform him if any thing contained therein is improper, or unlawful to be granted. Theſe grants, whether of lands, honours, liberties, franchiſes, or aught beſides, are contained in charters, or letters patent. (See Patents.) The *manner* of granting by the king does no more differ from that by a ſubject, than the conſtruction of his grants when made. 1. A grant made by the king, "at the ſuit of the grantee," ſhall be taken moſt beneficially *for* the king, and *againſt* the party; whereas the grant of a ſubject is conſtrued moſt ſtrongly *againſt the grantor*. It is therefore uſual to inſert in the king's grants, that they are made, not at the ſuit of the grantee, but "ex ſpeciali gratia, certa ſcientia, et mero motu regis;" and then they have a more liberal conſtruction. 2. A ſubject's grant ſhall be conſtrued to include many things, beſides what are expreſſed, if neceſſary for the operation of the grant. Thus, in a private grant of the profits of land for one year, free ingreſs, egreſs, and regreſs, to cut and carry away thoſe profits, are alſo incluſively granted. (Co. Litt. 56.) And if a feoffment of land was made by a lord to his villein, this operated as a manumiſſion (Litt. § 206.); for he was otherwiſe unable to hold it. But the king's grant ſhall not enure to any other intent, than that which is preciſely expreſſed in the grant. As, if he grants land to an alien, it operates nothing, for ſuch grant ſhall not alſo enure to make him a denizen, that he may be capable of taking by grant. (Bro. Abr. tit. patent. 62. Finch. L. 110.) 3. When it appears, from the face of the grant, that the king is miſtaken, or deceived, either in matter of fact or matter of law, as in caſe of falſe ſuggeſtion, miſinformation, or miſrecital of former grants; or if his own title to the thing granted be different from what he ſuppoſes; or if the grant be informal; or if he grants an eſtate contrary to the rules of law; in any of theſe caſes the grant is abſolutely void. (Freem 172. Finch. 101, 102.) To prevent deceits of the king, with regard to the value of the eſtate granted, it is particularly provided by the ſtatute 1 Hen. IV. c. 6. that no grant of his ſhall be good, unleſs, in the grantee's petition for them, expreſs mention be made of the real value of the lands. Blackſt. Com. vol. ii.

GRANTHAM, in *Geography*, a townſhip of Upper Canada, in the county of Lincoln, fronting lake Ontario.

Grantham, a market and borough town in the ſoke, or wapentake, of the ſame name, in Keſteven diviſion of the county of Lincoln, England, is ſituated on the ſide of the river Witham, on the ancient Roman road called Ermine ſtreet. The town compriſes four principal ſtreets. The church is an elegant ſtone ſtructure, conſiſting of a nave and two ſpacious aiſles, with large handſome pointed windows, and is celebrated for its lofty ſpire, which is 273 feet in height. The ſtyle of architecture appears to be that of the thirteenth century; though Mr. Gough obſerves that the church was endowed by Hugh, biſhop of Lincoln, A.D. 1100.

1100. Beneath the church is a chancel-houſe, filled with human ſkulls and other bones. Among ſeveral handſome monuments in this edifice, are, one to ſir Thomas Bury, chief baron of the exchequer in the time of George I, and one to ſir Dudley Ryder, chief juſtice of the King's Bench, in the ſucceeding reign. The font exhibits a fine ſpecimen of ancient ſculpture.

Grantham was incorporated under a charter granted by Edward IV. in 1463; when it firſt returned members to parliament; the repreſentatives are choſen by the freemen of the borough. The civil government is veſted in an alderman, a recorder, 12 common burgeſſes, a coroner, an eſcheator, and twelve ſecond men, who are the common council. The juriſdiction of this corporation extends over the whole ſoke, comprehending twelve villages, and the alderman acts as ſheriff of the town and ſoke, the ſheriff of the county having no authority within the ſoke and diſtrict thereof. The guildhall was rebuilt under an act of parliament in 1787. A free-ſchool was founded here by Richard Fox, biſhop of Wincheſter, and further endowed by king Edward VI.; this ſchool attracts attention, from the circumſtance of its having been a place of education to that luminary of ſcience, ſir Iſaac Newton. Near the ſouth entrance into the town, on St. Peter's hill, formerly ſtood an elegant croſs, erected by king Edward I., in memory of Eleanor his queen, who died in 1290; this being one of the places where the corpſe was laid in ſtate in its way for interment in Weſtminſter Abbey. Grantham is diſtant from London 111 miles N., has a well ſupplied market on Saturdays, and five annual fairs. In the return under the late population act, the number of houſes is 631, occupied by 3303 inhabitants.

A canal has been lately cut from Grantham to the river Trent, an extent of 25 miles. It is ſupplied with water by means of large reſervoirs made for that purpoſe. The chief articles conveyed by this navigation are corn and coals. Turner's Hiſtory of the Soke of Grantham, &c. Beauties of England and Wales, vol. ix.

GRANTHAM *Canal*, is the parliamentary name of an inland navigation about 33 miles long, in the counties of Nottingham, Leiceſter, and Lincoln, of which we gave an account in our article CANAL, and nothing material has occurred to be added thereto.

GRANTOWN, a town of Scotland, in the county of Inverneſs; 17 miles S. of Fores.

GRANVILLE, GEORGE, baron Landſdown, in *Biography*, a nobleman chiefly remembered as a poet, born in 1667, was ſon of Barnard Greenvill, one of the diſtinguiſhed family of Greenville or Granville, the latter mode of ſpelling the name being introduced by the ſubject of this article, who is thereby ſeparated from the reſt of his houſe. He ſhewed very early talents, and was entered, in his 12th year, at Trinity college, Cambridge. In the ſame year, he wrote a copy of verſes on the ducheſs of York's viſit to the univerſity, and on the acceſſion of James II. he offered incenſe to the new prince in three ſhort pieces, of which Dr. Johnſon ſays, "the firſt is profane, and the two others ſuch as a boy might be expected to produce." In 1688, when an invaſion was threatened, he was deſirous of devoting his life to the ſervice of James, and requeſted his father to preſent him to the king for that purpoſe. The revolution ſucceeded, and being poſſeſſed of neither intereſt nor conſiderable fortune, he lived in literary retirement. During this period his dramatic works were chiefly compoſed and acted. The firſt of theſe was "The Gallants," ſaid by himſelf, by way of apology, to have been written at an age when ſome perſons are but beginning to ſpell. This was afterwards brought forward in a more correct form, under the title of "Once a Lover and always a Lover." His tragedy of "Heroic Love," founded on the fable of Homer's Iliad, was acted the ſame year with great applauſe from the wits and critics. On this occaſion he was complimented in a copy of verſes from the pen of Dryden. When queen Anne came to the crown, Mr. Granville emerged from the political obſcurity in which he had lived: his fortune was increaſed by the death of his father, and that of his uncle, who left him an annuity. He was now elected a member of parliament for the borough of Fowey, and feeling the common ardour of his countrymen of all parties againſt the ambition of Lewis XIV., he joined other literary perſons in a tranſlation of the Philippics of Demoſthenes, to rouſe the nation to oppoſe the Philip of modern times. By the death of his elder brother ſir Bevil Granville, in 1706, he ſucceeded to a good eſtate, and he continued to ſerve in parliament, ſitting as knight of the ſhire for the county of Cornwall. On the change of adminiſtration in 1710, he was appointed ſecretary of war in the room of ſir Robert Walpole. He married in the ſame year Mary, the daughter of the earl of Jerſey, then widow of Thomas Thynne, eſq. Shortly after this he was introduced into the houſe of peers by the ſtyle and title of lord Landſdown, baron of Biddeford, at the memorable creation of twelve peers, in one day, *viz.* December 31, 1711. The elevation, however, of lord Landſdown was not one of thoſe which appeared very extraordinary, as two peerages had become extinct in the Granville family. On account of his principles and conduct he ſtood high in favour of the queen, who made him a privy counſellor, comptroller and treaſurer of the houſehold; but the acceſſion of George I. put an end to the power of his party, and deprived him of his place. He remained ſteady to his former connections, proteſting againſt meaſures which he deemed unconſtitutional, and in conſequence of his zeal he was regarded with a ſuſpicious eye, and was reckoned by people in power as a diſaffected man. Upon the breaking out of the rebellion in 1715, he was committed to the Tower, and kept confined in that fortreſs till February 1717, when he obtained his liberty and reſumed his ſeat in the houſe of lords. In 1719 he oppoſed with violence the propoſed repeal of the bill to prevent occaſional conformity; his ſpeech on the ſubject he afterwards printed. Subſequently to this a derangement in his private affairs, owing to the want of economy, obliged him to ſpend ſome years on the continent. During his abſence, the firſt volume of biſhop Burnet's "Hiſtory of his own Times," making its appearance, lord Landſdown undertook the vindication of the duke of Albemarle and the earl of Bath, from ſome aſperſions thrown upon them in that work. He alſo took occaſion to vindicate his great uncle, ſir Richard Greenville, from the unfavourable repreſentations of his conduct by lord Clarendon, and archdeacon Echard. On this occaſion he publiſhed two tracts in 1732. In the ſame year he publiſhed a ſplendid edition of his works, leaving out a comedy, which, on account of its licentiouſneſs, had been objected to, and he alſo omitted to inſert his ſpeech againſt occaſional conformity. He now felt reconciled to the meaſures of government, and to the change in the ſucceſſion, which formerly he had regarded with horror. He went to court, and was graciouſly received by queen Caroline, to whom he preſented his works, with ſome elegant lines written in a blank leaf. He died Jan. 30, 1735, in his 64th year. In private life, lord Landſdown was amiable, polite, and candid. He was liberal in patronizing literary merit, and had the credit of being one of the firſt to recognize the riſing powers of Pope, who repaid him for his kindneſs by his dedication of Windſor

Foreſt. His own talents, as a poet, were not of the firſt order, but his works are ſtill read with pleaſure. He is chiefly known as a writer of amatory pieces, moſt of which are addreſſed to Myra, the counteſs of Newburgh, the object of his youthful paſſion. Theſe are not either highly poetical nor ſtrongly expreſſive of feeling. Johnſon characterizes his "Eſſay on unnatural Flights in Poetry," as poſſeſſing didactic merit, and his "Britiſh Enchanters," as lively and pleaſing. He ſeems to think favourably likewiſe of his epilogues and prologues. Biog. Brit. Johnſon's Lives of the Poets.

GRANVILLE, in *Geography*. See GRANDVILLE.

GRANVILLE, a county of North Carolina, in Hillſborough diſtrict, S. of Virginia, containing 14,015 inhabitants, of whom 6106 are ſlaves. Its chief town is Williamſburg.—Alſo, a townſhip of the county of Annapolis, in Nova Scotia, N. of Annapolis river, on the bay of Fundy, 30 miles long; firſt ſettled from New England.—Alſo, a townſhip of Hampſhire county, Maſſachuſetts, about 14 miles W. of Springfield; incorporated in 1754, and containing 2309 inhabitants.—Alſo, a poſt-town in Waſhington county, New York, containing 3175 inhabitants.

GRANVILLE, or *Greenville*, a flouriſhing town in Mecklenburg county, Kentucky.

GRANVILLE'S *River*, a river of the iſland of Egmont, or New Guernſey, which runs into the ſea, S. lat. 10° 42'. E. long. 163° 58'.

GRANULATED OIL. See OIL.

GRANULATION, in *Chemiſtry*, an operation performed on metals, whereby they are reduced into ſmall grains or globules.

It is done by melting them, and when in fuſion, caſting them from a certain height into cold water; in which they congeal into granules, as required, and are hereby rendered more eaſy to be diſſolved. The beſt way is to pour the fluid metal through a cullender, or a new birchen broom, or to agitate the water with a broom, thus giving it a circular motion while the metal is poured in. Copper is granulated for making braſs in a cylindrical wooden reſervoir, four or five feet deep, in which a circular braſs or copper bottom may be raiſed or lowered by means of a chain. The reſervoir is covered with a copper lid, in the middle of which is a hole half a foot in diameter, intended to receive an iron ladle pierced with holes and coated with clay. The reſervoir being filled with water, the melted copper is poured through the holes in the ladle into the water; where it is broken by its fall into ſmaller drops or grains, rendered ſolid by the cold water, and collected in the moveable bottom, which is raiſed by the annexed chain, that the granulated copper may be taken out. Macquer, Dict. Chem. Eng. edit. art *Braſs*. See BRASS.

Lead, tin, and braſs, which are very brittle, when they are ſo hot as to be almoſt fuſed, may be granulated by pouring them, in a ſtate of fuſion, into a box, the inner ſurface of which is rubbed with powdered chalk, and by ſhaking the box: the metals in the box are no ſooner become ſolid, and conſequently very brittle, than they are ſhivered, by being daſhed againſt the ſides of the veſſel into a fine duſt. Silver and gold, and the more tenacious metals, muſt be granulated in either of the firſt methods above-mentioned, with water. Cramer, Art of Aſſ. p. 70.

The term granulation is alſo applied to *gun-powder*: which ſee.

The granulation of common fowling ſhot conſiſts merely in cauſing the fuſed metal to fall in equal ſpherical drops into water. The lead is melted with the addition of a ſmall proportion of arſenic, which being reduced to a metallic ſtate, by means of greaſe ſtirred in during the fuſion, renders it leſs fluid. An oblong ſhallow veſſel of iron, perhaps 10 inches wide, 14 long, and 2½ deep, called a "Card," whoſe bottom is pierced with holes, proportionate to the ſize of the ſhot, is placed at the height of from one to three inches, over the ſurface of a tub of water, covered with a thin film of oil. The card is previouſly heated to the temperature of the metal, by immerging it in the cauldron; and a ſtratum of ſoft droſs or ſcoriæ, found on the ſurface of the fuſed alloy, is then placed on its perforated bottom, and being ſlightly preſſed down with the ladle, forms a kind of filter, which partly chokes up the apertures, and prevents the metal from flowing through them in continuous ſtreams. The fuſed metal is then poured by ladle-fulls into this veſſel, and appears, notwithſtanding, to run through it with conſiderable velocity; ſo that it ſeems difficult to believe, that it falls in ſeparate drops, till one is convinced by taking up a quantity of ſhot from the bottom of the water. The imperfections to which this ſhot is ſubject, are remedied in the patent ſhot, the manufacture of which differs from that of the preceding kind, in the addition of a larger portion of arſenic, which varies according to the quantity of the lead, in dropping it from ſuch a height, that it becomes ſolid before it enters the water, which is from 40 to 100 feet. Beſides, it is firſt dried and ſifted. It is then *boarded*, which conſiſts in ſcattering it on ſeveral poliſhed ſlabs, or trays of hard wood, with rims in the form of a π, except that the ſides converge towards the lower part, to which a ſlight inclination and alternate motion in their own planes are given by boys employed in the manufacture. The ſhot, whoſe form is imperfect, are detected by the ſluggiſhneſs of their motion, and remain behind, whilſt the others roll off from the board. The laſt operation is the poliſhing; which is performed by agitating the ſhot with the addition of a very ſmall quantity of black-lead, not exceeding two ſpoonfuls to a ton, in an iron veſſel, turning on an horizontal axis, like a barrel churn. It does not appear that any higher degree of perfection than that which is thus attained remains to be deſcried. The argentine brilliancy of the ſhot when newly made, the beautiful accuracy of its form, and the curious inſtance of inanimate tactics which it preſents when ſcattered on a plate, renders it even an agreeable object of contemplation. Nicholſon's Journal, vol. 1. 4to.

GRANULATION. In *Surgery*, granulations are the ſmall eminences of new animal matter, with which the cavities of ſores and wounds become filled up in the proceſs of healing. Granulations, according to Mr. Hunter, are formed by an exudation of the coagulating lymph from the veſſels, into which new ſubſtance the old veſſels very probably extend, at the ſame time that entirely new ones are generated in it. Hence granulations are exceedingly vaſcular, perhaps more ſo than almoſt any other animal ſubſtance. Mr. Hunter informs us, that he noticed upon a ſore a white ſubſtance, exactly ſimilar in every viſible reſpect to coagulating lymph. He did not attempt to wipe it off, and the next day of dreſſing he found this very ſubſtance vaſcular; for, on touching it with a probe, it bled freely. He obſerved the ſame appearance on the ſurface of a bone that had been laid bare. He once ſcraped off ſome of the outſide of one of the bones of the foot, in order to ſee if the ſurface would granulate. The following day he remarked, that the ſcraped part was covered with a whitiſh ſubſtance, having a tinge of blue. When he paſſed his probe into it, he did not feel the bone bare; but only its reſiſtance. He conceived this ſubſtance was coagulating lymph, thrown out in conſequence of inflammation,

flammation, and that it would be forced off when ſuppuration came on; but on the ſucceeding day he found it vaſcular, having all the appearance of healthy granulations.

The veſſels of granulations firſt paſs to their baſis from the original parts, whatever theſe may be, and then run in nearly parallel lines to their external ſurface, where they ſeem as if they ended.

The ſurface of the new ſubſtance continues to have the ſame diſpoſition for the ſecretion of pus, as the parts from which it itſelf was produced. Granulations are very convex, which is an appearance the very reverſe of what happens in ulceration, or while a ſore is increaſing in ſize. They appear rough, in conſequence of having a great many points or ſmall eminences, and they are deemed the more healthy, the ſmaller ſuch points are.

Healthy granulations are of a deep florid red colour, a circumſtance which might lead one to ſuſpect, that the colour was principally owing to the arterial blood; but Mr. Hunter was of opinion, that this appearance only denoted a briſk circulation in the new-formed ſubſtance, the blood not having time to become dark.

When granulations are naturally of a livid red, they are commonly unhealthy, and ſhew a languid circulation. Such appearances may often be induced by poſition, and we frequently ſee it take place on ſores of the leg, when the limb is not kept in a horizontal poſture. In this circumſtance, the new-formed veſſels are incapable of ſupporting the increaſed column of blood, and of acting upon it. The ſtagnation allows the change of colour to happen, and the alteration, in all probability, takes place both in the arteries and veins. Here may be ſeen the reaſon why ſore legs are frequently very backward in healing, when the patient is ſuffered to put his foot on the ground, or to walk about.

Healthy granulations, ſituated on an expoſed or flat ſurface, riſe nearly even with the ſurface of the ſurrounding ſkin, and often a little higher; and in this ſtate they are always of a florid red colour. When they exceed this height, and aſſume a growing diſpoſition, they are then unhealthy, and they become ſoft and ſpongy, without any diſpoſition to form ſkin.

Granulations always have the ſame diſpoſition as the parts upon which they are formed; and take on the ſame mode of action. If it is a diſeaſed part, they are diſeaſed; and if the diſeaſe be of any ſpecific kind, they are alſo of the ſame nature, and, of courſe, produce matter of the ſame quality.

When granulations are healthy, they are always prone to unite with each other, the great uſe of which is to bring about the union of parts, ſomewhat like what is the reſult of union by the firſt intention. See WOUNDS.

The diſpoſition which granulations have to unite with each other upon coming into contact, without the appearance of any intermediate animal ſubſtance, is perhaps effected, as Mr. Hunter conjectures, in the following manner. When two ſound granulations approach together, the mouths of the ſecreting veſſels of the one coming to oppoſe the mouths of ſimilar veſſels of the other, they are ſtimulated into action, which is mutual; ſo that a kind of ſympathetic attraction takes place, and as they are ſolids, the attraction of coheſion is eſtabliſhed between them. This has been termed inoſculation. The veſſels thus joined are altered from ſecreting to circulating. There are ſome other ſurmiſes hazarded by Mr. Hunter reſpecting the rationale of this minute proceſs of nature; but the curious reader muſt refer for them to the author's own relation of the ſubject.

Mr. Hunter informs us, that he has ſeen two granulations on the head, *viz.* one from the dura mater after trepanning, and the other from the ſcalp, unite over the bare one, which was between them, ſo ſtrongly in twenty-four hours, that ſome force was required to ſeparate them, and when ſeparated, they bled.

The inner ſurface of the ſkin, in caſes of abſceſſes, not only does not readily granulate, but does not readily unite with the granulations underneath. Hence the frequent formation of fiſtulæ and ſinuſes.

Unhealthy granulations have not an equal tendency to unite with each other: a ſmooth ſurface is formed, which continues to ſecrete matter. Thus, Mr. Hunter regarded the internal ſurface of a fiſtulous ulcer as, in ſome degree, ſimilar to the inner ſurface of the urethra, when it is forming the diſcharge commonly called a gleet. Such ſores have no diſpoſition in their granulations to unite, and nothing can produce an union between them, but altering the diſpoſition of theſe granulations, by exciting a conſiderable inflammation and probably ulceration; ſo as to form new granulations, and by this means give them a chance of falling into a ſound ſtate.

It is alſo noticed by Mr. Hunter, that granulations are not furniſhed with ſo much power as parts poſſeſs, which are originally formed. Hence they more readily ulcerate and ſlough. He ſtates, that they not only ſhew the condition of the part in which they grow, or the condition in which they are themſelves, but alſo, how the conſtitution is affected by many diſeaſes.

The ſame author has made ſome obſervations reſpecting the longevity of granulations. He ſays, that they often ſeem to be formed with only ſtated periods of life, and thoſe much ſhorter, than the life of the part, on which ſuch granulations are ſituated. Their life, indeed, does not appear to be ſo ſhort, when cicatrization can be accompliſhed; but while a ſore is in a granulating ſtate, they frequently periſh without any viſible cauſe. Thus, ſays Mr. Hunter, a perſon may have on his leg a ſore, which granulates well, the granulations have a healthy appearance, the ſkin is forming round the edges, and every thing promiſes well, when, all at once, the granulations become livid, loſe their life, and immediately ſlough off. In ſome inſtances, they are deſtroyed, partly by ulceration, and partly by mortification. Then new granulations are frequently produced, and go through ſimilar changes. Sometimes this happens three or four times in the ſame perſon. Mr. Hunter in vain tried various methods for rendering the granulations in ſuch caſes more durable.

Suppuration and granulation are eſſential for the cicatrization and union of almoſt every wound, which has not been united by the firſt intention: a few ſmall wounds and ſcratches, which heal under a ſcab, being the only exceptions.

Our author, in the following ſection of his treatiſe on the blood, notices, that cicatrization ſeems to be in view immediately after the granulations are formed. The parts which had receded, in conſequence of a breach being made in them, by their natural elaſticity, and, probably, by muſcular contraction, now begin to be brought together by this new ſubſtance, which ſoon contracts. The contraction takes place in every joint, but principally from edge to edge, which brings the circumference of the ſore towards the centre, ſo that the ſore becomes ſmaller and ſmaller, although little or no new ſkin may be formed.

The tendency in the granulations to contract is, in ſome degree, proportioned to the general healing diſpoſition of the ſore, and the looſeneſs of the parts, on which they are formed. When new ſkin cannot be produced, the granulations do not ſo readily contract, and, therefore, Mr. Hunter infers, that their contraction and the production of ſkin are probably effects of one cauſe. The induration, occaſioned by inflammation, retards the contraction of granulations, though Mr. Hunter was inclined to think, that the circumſtance did not ariſe ſo much from a mechanical principle, as from the diminution of the diſpoſition to the proceſs occaſioned by the inflammation itſelf. Granulations, however, as the ſame writer explains, are ſometimes undoubtedly retarded in their contraction by mechanical cauſes, when formed on parts naturally fixed, ſuch as a bone; for inſtance, on the ſkull, the ſhin, &c.

When, by reaſon of a loſs of ſubſtance, there is a deep hollow ſore, and the contraction of the granulations is conſiderably advanced, before they have had time to riſe as high as the ſkin, the edges of the latter part are generally drawn down, and tucked in by it, in the direction of the excavated ſurface of the ſore.

If it is a cavity or abſceſs, which is granulating, with only a ſmall opening, as often happens when the ſurgeon has neglected to make a free aperture, the whole circumference contracts, like the bladder of urine, till little or no cavity remains; and if any cavity is left, when the granulations can contract no further, they unite with ſuch as are oppoſite to them.

This contraction in the granulations, ſays Mr. Hunter, is continued till the whole of a ſore is healed, or ſkinned over; but it happens in the greateſt degree in the beginning, when there is leſs reſiſtance in the ſurrounding parts.

The contraction of granulations may often be aſſiſted by art, namely, by uſing bandages, which tend to puſh, draw, or keep the ſkin near to the ſore which is healing.

Beſides the contractile power of the granulations, there is a ſimilar power in the ſurrounding edge of the cicatrizing ſkin, which aſſiſts the contraction of the granulations, and is even more conſiderable, drawing the mouth of the wound together like a purſe, and ſometimes, when the ſurface of the ſore is high, graſping the granulations.

The contractile power of the ſkin is chiefly confined to the very edge, where it is healing. The ſurrounding old ſkin either does not contract at all, or not much, as is evident from its being thrown into folds and plaits, while the new ſkin is ſmooth and ſhining. The original ſkin, having little or no power of contraction, is a reaſon why round ſores cannot ſo readily heal as long ones.

Mr. Hunter has explained, that the uſes, ariſing from the contraction of granulations, are various. It facilitates the healing of a ſore, as there are two operations going on at the ſame time, *viz.* contraction and ſkinning. It avoids the formation of much new ſkin, an effect which is very evident in all ſores which are healed, eſpecially in ſound parts. When a thick thigh, ſeven or eight inches in diameter, has been amputated, the ſurface of the ſore is of the ſame width; yet, in the end, the cicatrix will be no broader than a crown-piece, in conſequence of the old ſkin becoming drawn over the ulcer, by the contractile power of the granulations. The advantage of this is conſiderable, ſince ſuch parts as are originally formed are always much fitter for the purpoſes of life than thoſe which are newly formed.

After all, a ſore is covered with ſkin, the ſubſtance, which is the remains of the granulations on which the new ſkin is formed, ſtill continues to contract, till hardly any thing more is left than what the new ſkin ſtands upon. This is a very ſmall part, in compariſon with the firſt formed granulations, and, in time, it loſes moſt of its apparent veſſels, becoming white and ligamentous. All new-healed ſores are at firſt redder than the common ſkin, but afterwards become much whiter.

As the granulations contract, the ſurrounding old ſkin is ſtretched to cover the part which is deprived of integuments. At firſt, the ſkin is brought little further than into the poſition from which it had receded, on the occurrence of the wound; but afterwards it becomes drawn much more conſiderably, being ſtretched and elongated. See Hunter's Treatiſe on the Blood, Inflammation, &c. chap. 7.

GRANULES, in *Geology*, is a term which Mr. Whitehurſt, ("Enquiry," 1ſt edit. p. 180.) and others, employ to expreſs the grains or minute lumps of ſtony matter, compoſing the ſand uſually found on the ſurface of valleys, and which is formed by attrition and the grinding down of ſtones of different kinds.

GRANULOSE Roots, are thoſe compoſed of ſmaller knobs than the grumoſe ones, and reſembling ſo many grains of corn; of this ſort is the white ſaxifrage.

GRANUM Viride, in *Botany*, a name given by ſome authors to the turpentine-tree. The fruit of this tree is reddiſh while unripe; but as it ripens, it becomes of a deep blueiſh-green colour, and hence the name.

GRANZA, in *Geography*, a town of Africa, in the country of Magadoxa.

GRANZOW, a town of the Ucker-Mark of Brandenbury; 8 miles S. E. of Prenzlow.

GRAO, a port of Spain, in Valencia, which carries on a coaſting trade along the Mediterranean; on one ſide, on the coaſts of Catalonia, Rouſſillon, Languedoc, as far as Marſeilles; and on the other ſide, to Alicant, Carthagena, and Malaga: ſome veſſels even paſs the ſtraits of Gibraltar, into the Atlantic, and go to Cadiz; and ſometimes they go round Portugal as far as the ports of Galicia. The largeſt of theſe ſhips are from 50 to 60 tons, each having a crew not exceeding 11 men. They carry out wines, ſilk, wool, dry fruits, and kali; and return with linens, woollens, ironmongery, ſpices, and corn. Grao is pleaſant in ſummer, on account of the ſea-baths, which draw together a great number of people for health or amuſement.

GRAPE, the fruit of the vine. See Vine and Wine. See alſo Currants and Raisins.

Grape *Hyacinth.* See Hyacinth.

Grape, *Mangrove* or *ſea-ſide.* See Coccoloba.

Grapes, *Wolf* See Lycostaphylæ.

Grape-*galls*, in *Natural Hiſtory*, a name given by authors to a ſpecies of protuberances, reſembling cluſters of grapes, and when ripe of a reddiſh colour, which are found hanging from the oak at ſome ſeaſons of the year. Theſe are genuine galls, though of a peculiar kind, and owe their origin to a very ſmall four-winged black fly. See Galls.

Grape-*ſhot*, in *Artillery*, is a combination of ſmall ſhot, put into a thick canvas bag, and corded ſtrongly together, ſo as to form a kind of cylinder, whoſe diameter is equal to that of the ball adapted to the cannon. The number of ſhot in grape varies according to the ſervice or ſize of the guns: in ſea-ſervice nine is always the number; but by land it is increaſed to any number or ſize, from an ounce and a quarter in weight to three or four pounds. In ſea-ſervice, the bottoms and pins are made of iron, whereas thoſe uſed by land are of wood.

Grape-*ſtone*, Botrites, is a ſort of ſtalagmites, which effervesces with acids, according to Dr. Grew, "Rarities of Greſham College," p. 304. It is alſo the name of certain botroidal ſtalactites, which are ſometimes met with, pendant from the roofs of caverns in lime-ſtone diſtricts.

Grapes, in the *Manege*, a term uſed to ſignify the arrets or mangy tumours that happen in a horſe's legs. See Arrets.

GRAPHICAL Perspective, in *Optics*, is an inſtrument deſcribed by Mr. Martin, conſiſting of a tube containing two convex lenſes, which are placed at twice their focal diſtance from each other; and in their common focus is another glaſs, divided into equal parts with the point of a diamond. Though this inſtrument does not magnify any object, yet the angle under which an object is ſeen is eaſily known by it; and ſince this angle varies with the diſtance of objects, it is eaſily applied to the purpoſe of meaſuring inacceſſible heights and diſtances; and ſince the field of view is divided into equal ſquares, it is uſeful in drawing the perſpective appearance of objects. Moreover, as all foreign light is excluded by the tube in which theſe lenſes are incloſed, pictures ſeen through it have a fine relievo, on which account, and alſo becauſe objects appear inverted through it, the images of a camera obſcura are viewed with it to peculiar advantage. If a lens of a greater focal length be fixed at a proper diſtance from the centre of the tube, this inſtrument will be a teleſcope, and will magnify the prints which are looked at through it; and if a ſmall lens be uſed, it will be a microſcope, and the ſame micrometer will ſerve for them both. Martin's Optics, chap. xvii. p. 280, &c.

GRAPHIDA, in *Natural Hiſtory*, a name by which ſome authors have called the *morochthus*, or French chalk.

GRAPHIS, in *Botany*, from γραφω, *to write*, a name invented by Adanſon, who is pleaſed to ſpell it *grafis*, and adopted by Ehrhart, for the various ſpecies comprehended under the *Lichen ſcriptus* of Linnæus, and which conſtitute the very diſtinct genus of *Opegrapha* in Acharius; ſee Eng. Bot. v. 25, 26. t. 1753, &c.

GRAPHISCUS, in the *Writings of the Ancients*, a name given to an inſtrument uſed for extracting darts from wounds. It is ſaid to have been the invention of Diocles, and is deſcribed by Celſus.

GRAPHITE. See Plumbago.

GRAPHOIDES, γραφοειδης, in *Anatomy*, an appendage of the bones of the temples, long, ſmall, ſharp, and a little crooked, like a cock's ſpur; called alſo *ſtyloides*.

The ſame name is ſometimes alſo applied to the muſculus digaſtricus.

Likewiſe to an extenſion of the brain, reſembling a writing pen.

GRAPHOMETER, a name which ſome authors, particularly the French, give to a ſurveying inſtrument, by us commonly called a *ſemicircle*; which ſee. Mr. Nicholſon, in the fifth volume of his "Journal," 8vo. has deſcribed, and illuſtrated by appropriate figures, a ſubterranean graphometer, invented by M. Komarzowſki, F. R. S. and preſented to the National Inſtitute of France. It is a ſimple conſtruction of the common *theodolite* (which ſee), and is calculated to anſwer the author's intentions in operations like thoſe of mining, where great accuracy is not required. In vol. i. of the ſame "Journal," we have the deſcription of an inſtrument reſembling a graphometer, invented by Cit. Carangeau, for determining the mutual inclination of the faces of a cryſtal, or its prominent angles; it conſiſts of two concentric, equal quadrantal arcs joined by a hinge; to which are applied compaſs-legs or radii, capable of being ſhortened to apply to ſmall cryſtals, &c. See Goniometer. See alſo *Plate* VI. *Cryſtallography*, *fig.* 93.

GRAPNEL, or Grapling, on *Ship-board*, a kind of ſmall anchor for boats or gallies to ride by. It differs from other anchors, as having four or five flukes and no ſnack, though there are ſome with three flukes, with which they uſe to ſweep for hawſers or ſmall cables. In men of war alſo, the grapnels, or at leaſt a lighter kind of them, whoſe flukes are furniſhed with ſtrong barbs on their points, are uſed to be thrown into an enemy's ſhip, in order to catch hold of ſome of her gratings, rails, gun-wales, &c. this is done in order to boarding of her. They are particularly uſeful in fire-ſhips, and called fire-grapplings.

GRAPPLE, in the *Manege*. A horſe is ſaid to grapple with one or both legs, when he catches or raiſes them more haſtily and higher than ordinary, as if he were curvetting.

GRAPTOLITHI, in *Natural Hiſtory*, are the petrificata ficta of Linnæus and others; as dendritæ, landſcape-marble, dendropotamites, &c. all which, according to Mr. William Martin, "Outlines," p. 8. ſhould be excluded from the liſt of extraneous foſſils.

GRASS, Gramen, in *Botany*, See Gramina.

To enumerate all the ſpecies of graſs which are found growing naturally in England, would greatly exceed the bounds which can be allowed for this article; it will ſuffice, therefore, to mention a few ſpecies, which are either uſed in medicine, or cultivated as a pabulum for cattle; for there is ſcarcely a paſture in this country where great numbers of different ſpecies are not to be found intermixed. Mr. Ray has ranged them in the following order, *viz.* wheat-graſs, rye-graſs, darnel-graſs, panick-graſs, canary-graſs, fox-tail graſs, cat's-tail graſs, hedge-hog graſs, creſted-graſs, oat-graſs, cock's-foot-graſs, buck-graſs, and millet-graſs. Theſe and other graſſes Linnæus has arranged into diſtinct genera. See the following articles:

Grass, *Arrow-headed.* See Triglochin.

Grass, *Bent.* See Agrostis.

Grass, *Bird.* See Bird-*graſs*.

Grass, *Canary.* See Phalaris.

Grass, *Capon's-tail.* See Festuca.

Grass, *Cat's-tail.* See Phleum.

Grass, *Clover.* See Trefoil.

Grass, *Cock's-tail.* See Dactylis.

Grass, *Cotton.* See Eriophorum.

Grass, *Couch.* See Triticum.

Grass, *Creſted.* See Dog's-*tail-graſs* and Cynosurus.

Grass, *Dog's.* See Triticum and Agrostis.

Grass, *Sea-dog's*, a name ſometimes given to the double ſpiked ſecale, or rye. See Secale.

Grass, *Dog's-tail.* See Dog's-*tail-graſs* and Cynosurus.

Grass, *Feſcue.* See Festuca.

Grass, *Fox-tail.* See Alopecurus.

Grass, *Gooſe.* See Asperugo.

Grass, *Hair.* See Aira.

Grass, *Hare's-tail.* See Lagurus.

Grass, *Knot.* See Polygonum.

Grass, *Knot, German.* See Scleranthus.

Grass, *Knot, Mountain*, and *Verticillate.* See Illecebrum.

Grass, *Love*, or *Quaking.* See Briza.

Grass, *Meadow.* See Poa.

Grass, *Hard meadow.* See Cynosurus.

Grass, *Millet.* See Milium.

Grass, *Oat*, a name given to a ſpecies of the feſtuca. See alſo Avena.

Grass, *Panic.* See Panicum.

Grass *of Parnaſſus.* See Parnassia.

Grass, *Pepper.* See Pilularia.

Grass, *Pudding.* See Mentha.

Grass, *Quaking.* See Briza.

Grass, *Rattle.* See Pedicularis.

Grass, *Ruſh.* See Scirpus.

Grass, *Rye*, or *Ray.* See Lolium and Hordeum.

Grass, *Scorpion.* See Scorpiurus.

Grass, *Scorpion, Mouſe-ear.* See Myosotis.

Grass, *Scurvy.* See Cochlearia.

Grass, *Shave.* See Equisetum.

Grass, *Silk.* See Apocynum.

Grass, *Sword.* See Gladiolus.

Grass, *Trefoil.* See Trefoil.

Grass, *Vernal.* See Anthoxanthum.

Grass, *Vetch.* See Lathyrus.

Grass, *Viper's.* See Scorzonera.

Grass, *Whitlow.* See Draba.

Grass, *Whitlow, Rue-leaved.* See Saxifraga.

Grass, *Worm.* See Spigelia.

Grass, *Wrack.* See Zostera.

Grass, in *Agriculture,* a general name applied to thoſe herbaceous plants that are employed in the feeding and fattening of neat cattle, ſheep, &c. It has been long ſince remarked in an able tract on the graſſes of this country, "that much of our meadow and paſture-land may be rendered infinitely more valuable than it is at preſent, by the introduction of ſome of the beſt graſſes which we poſſeſs; and that this is an opinion which has long prevailed among many of the more enlightened agriculturiſts of the preſent age, ſome of whom have endeavoured to excite the huſbandman to collect and cultivate ſeeds of this ſort, by writings fraught with the soundeſt reaſoning; while others have attempted to attract him by the offers of well-directed premiums; but that hitherto neither the writings of the one, however convincing, nor the premiums of the other, however alluring, have, as the author thinks, been productive of the deſired effect." And "Mr. Stillingfleet ſays, it is wonderful to ſee how long mankind has neglected to make a proper advantage of plants of ſuch importance, and which in almoſt every country are the chief food of cattle. The farmer, for want of diſtinguiſhing and ſelecting graſſes for ſeed, fills his paſtures either with weeds, or bad or improper graſſes; when by making a right choice, after ſome trials, he might be ſure of the beſt graſs, and in the greateſt abundance that his land admits of. At preſent, if a farmer wants to lay down his land to graſs, what does he do? He either takes his ſeeds indiſcriminately from his own foul hay-rick, or ſends to his next neighbour for a ſupply. By this means, beſides a certain mixture of all ſorts of rubbiſh, which muſt neceſſarily happen; if he chances to have a large proportion of good ſeeds, it is not unlikely but that what he intends for dry land may come from moiſt, where it grew naturally, and the contrary. This is ſuch a ſlovenly method of proceeding, as one would think could not poſſibly prevail univerſally; yet this is the caſe as to all graſſes, except the darnel-graſs, and what is known in ſome few counties by the name of the Suffolk-graſs (*poa annua*); and this latter inſtance is owing, it is believed, more to the ſoil than any care of the huſbandman. Now, continues he, would the farmer be at the pains of ſeparating once in his life half a pint or a pint of the different kinds of graſs-ſeeds, and take care to ſow them ſeparately; in a very little time he would have wherewithal to ſtock his farm properly, according to the nature of each ſoil, and might at the ſame time ſpread theſe ſeeds ſeparately over the nation by ſupplying the ſeed-ſhops. The number of graſſes fit for the farmer is, he believes, ſmall; perhaps half a dozen, or half a ſcore, are all he need to cultivate; and how ſmall the trouble would be of ſuch a taſk, and how great the benefit, muſt be obvious to every one at firſt ſight. Would not any one be looked on as wild, who ſhould ſow wheat, barley, oats, rye, peas, beans, vetches, buck-wheat, turnips, and weeds of all ſorts together? Yet how is it much leſs abſurd to do what is equivalent in relation to graſſes."

It is alſo aſſerted by Mr. Kent, that meadow and paſture-land is oftener neglected than ploughed ground, notwithſtanding it generally admits of a much greater proportion of improvement. The beſt graſſes cannot be collected at too great an expence; for he has ſeen a ſmall ſpot of land, in the middle of a large piece, which was laid down twelve or fourteen years ſince, by the writer noticed above, upon an eſtate in Herefordſhire, with ſome choice ſeeds, at the ſame time when the remainder of the field was laid down with common ſeeds; and that this ſpot is conſiderably better than the reſt. From theſe experiments, and his own obſervations, he is clearly of opinion, that any perſon who has land calculated for graſs may improve it, by this method of laying it down, to a much greater degree than he can in the common way. Dr. Anderſon has likewiſe obſerved, in the ſecond volume of his eſſays, that although it is probable, that none of the graſſes that have been hitherto cultivated by the farmer are of the moſt proper kind for paſturage; yet there is little reaſon to doubt but that many of the moſt valuable kinds for this purpoſe would admit of being cultivated with the ſame eaſe as ſome of thoſe are with which we are well acquainted, if they were properly ſeparated from others, and cultivated with equal care. But ſo long as we ſhall remain ignorant of the peculiar qualities of each kind of graſs, ſo as not to be able to diſtinguiſh the good from the bad, it is not ſurpriſing, that we ſhould remain firmly perſuaded that nature alone can provide valuable paſtures, and that age is ſo eſſentially neceſſary for bringing them to their ultimate perfection. For, if we allow our fields to remain uncultivated, without having ſowed them with any kind of graſs-ſeeds, it muſt ever happen, that the ſeeds of ſuch graſſes as are brought by the wind, or otherwiſe, from the neighbouring fields, will there take root, and in time eſtabliſh themſelves. And as it may ſometimes happen, that ſome of the moſt valuable paſture-graſſes may there abound; the field, in theſe caſes, will become filled with their ſeeds, and in due time may afford the moſt valuable paſture. But if bad kinds of graſſes ſhould abound in the neighbourhood more than the good, the field will as naturally become filled with the ſeeds of theſe uſeleſs plants. And as a number of theſe are hardy and abiding plants, if the field is once filled with them, the paſture will be, of conſequence, always of little value, if it ſhould be allowed to remain undiſturbed for any length of time. Let the reader, therefore, conſider how numerous the circumſtances are that muſt accidentally concur together before it is poſſible to expect a very fine field of paſture-graſs, if left to nature, and then he will perceive how improbable it is that all theſe ſhould concur to produce their full effect in any one field whatever. There muſt be no roots of bad graſſes, nor ſeeds of robuſt annuals, in the ſoil when it is left out from tillage; and the ſeeds of the moſt valuable kinds of graſſes muſt be in the neighbourhood in ſuch abundance as to fill the whole field ſufficiently at once. Nor is this all. For as there is, no doubt, a conſiderable variety of valuable kinds of graſs, ſome of which are naturally fitted to grow to perfection on one kind of ſoil, or upon that ſoil when in certain circumſtances, while others would thrive beſt upon another ſoil, or upon that ſoil only in certain peculiar circumſtances; it muſt ſo happen, that theſe very plants which are beſt adapted to the ſoil in the ſtate it may be in at the time, ſhould be found in abundance in the neighbourhood of the field. Neither muſt there be found near that, any ſort of robuſt quick-growing plant, the ſeeds of which, by being blown upon that field, might ſuddenly ruſh up and ſuffocate in their infancy theſe tender and valuable plants. Nor muſt there be found any bad kinds of graſs, that, by being eſtabliſhed along with the good in any proportion, might tend to diminiſh the value of the paſture.

" Now, let any one reflect on the infinite diverſity theſe few particulars may admit of, and think how utterly impoſſible it is that all the favourable circumſtances, without any of thoſe that are unfavourable, ſhould concur in any one caſe, and he will acknowledge, that thoſe who found their hope of obtaining the moſt valuable paſtures only upon the fortuitous concurrence of all theſe circumſtances, or who imagine that every paſture which is old muſt, on that account, of neceſſity be good, act in direct contradiction to the plaineſt dictates of reaſon and common-ſenſe. For, although it ſhould be allowed that the graſſes hitherto cultivated are not of the moſt proper ſort for forming good paſtures, and that therefore, on ſome occaſions, much better natural paſtures may be met with than could be formed by means of any of theſe; yet it by no means follows from thence, that if the farmer were perfectly acquainted with the value and diſtinguiſhing qualities of each kind of natural graſs, and knew the ſoil and culture that beſt agreed with it, the moſt proper manner of rearing it, and every other particular relating to the economy thereof, he might not perhaps have it in his power to form artificial paſtures as much excelling the natural as theſe laſt at preſent uſually exceeded the former. For were he poſſeſſed of the knowledge above ſuppoſed, he could at once fill the ſoil with the ſeeds of thoſe valuable graſſes which he knew were beſt adapted to it, and thus effectually exclude the admiſſion of every uſeleſs plant, or pernicious kind of graſs, that might be brought from the neighbouring fields by the wind, or other accidental cauſes.

" Let us, therefore, inſtead of contenting ourſelves on all occaſions with ſuch paſtures or graſs-lands as nature may afford, rather ſtudy to improve thoſe that are indifferent, by endeavouring to obtain a knowledge of ſuch plants as might afford the moſt valuable paſture, and cultivating theſe with aſſiduity and care. The inattention of the improving farmers in Great Britain to this ſubject has been truly amazing. But it is hoped the attempts that have been made by ſome late writers may have the effect of turning their attention to a ſubject of ſuch great importance; with regard to which, they will then doubtleſs make many valuable improvements. It is, however, to be feared, that till ſome attempt ſhall be made to aſcertain the particular qualities and peculiarities of the different kinds of graſſes, the public will be often impoſed upon by ſpecious accounts of new graſſes, which may be really poſſeſſed of few valuable qualities, and may very much tend to diſcourage the inquirer. It is conſequently neceſſary, to ſtrenuouſly endeavour to diſcover what are the particular purpoſes for which any one plant would be deemed valuable, and in what reſpects it might be looked upon as of no value at all: For, as there is no plant that can be alike uſeful on all occaſions, if we loſe ſight of this moſt neceſſary diſtinction, it may often happen, that we may attempt to rear a particular plant for purpoſes which it was never fitted to anſwer; and our want of ſucceſs in theſe trials may make it be entirely rejected, even in caſes for which it was extremely proper and beneficial.

It is ſtated that ray-graſs continues to be the only graſs whoſe ſeeds can be purchaſed for the purpoſe of laying down meadow and paſture-land; and how inadequate that graſs is for ſuch a purpoſe is known to every intelligent farmer. Why indeed the *lolium perenne* (ray or rye-graſs) ſhould originally have been made uſe of in preference to all the other graſſes, cannot, perhaps, be ſatisfactorily accounted for: moſt probably it owes its introduction to accident, or to its being a common graſs whoſe ſeeds were eaſily collected, rather than to its being preferred from any inveſtigation of its merits compared with the others. However this may be, there appears to be no reaſon for excluding the others; for it would appear exceedingly improbable, that of upwards of a hundred graſſes, taking the word graſs in its ſtrict ſenſe, that are growing wild in this country, the Author of nature ſhould have created only one as ſuitable to be cultivated for paſturage or fodder. Since this period, however, moſt of the natural graſſes have been cultivated for the purpoſe of affording ſeed, which may be procured genuine from many ſeedſmen in moſt places. Taking it for granted then, that there are other graſſes ſuperior in many reſpects to the ray-graſs, this queſtion naturally ariſes—How comes it that they have not found their way into general uſe? To this it may be anſwered, improvements in any ſcience, but more eſpecially in agriculture, are ſlow in their advances; and perhaps no claſs of men adheres more pertinaciouſly to old prejudices than that of farmers, and the difficulty of diſtinguiſhing the graſſes from each other has, too, no doubt, proved one grand obſtacle: many of theſe plants are ſo much alike, that the moſt diſcerning botaniſt is often at a loſs to know ſome of them apart: if ſo, how eaſily may the huſbandman be deterred from the arduous taſk! There is another cauſe alſo which may have operated againſt their introduction: graſſes, as well as other plants, have been frequently recommended from a partial and limited obſervation of them, by perſons who neither knew them well as botaniſts or agriculturaliſts, or who have recommended them, merely to gain by the credulity of the public. But, perhaps, the chief reaſon has been, that perſons who might be expected to make the improvements, have not had the means fairly put into their hands to make the experiment, there not having been any eaſy means of obtaining ſuch ſorts of graſs-ſeeds as may be moſt ſuitable for the purpoſe. It appears, however, that in the herbage of good meadows, or graſs-lands, there ſhould be a combination of produce, bateableneſs, and early growth. The firſt is, in moſt caſes, the agriculturaliſt's grand object—and no wonder, ſince it is the quantity chiefly which enables him to pay his rent, and ſupport his cattle: to obtain this, the judicious huſbandman ſpares no expence in labour or manure. But it does not follow that produce is to be attended to ſolely, or that, for its ſake, we are to cultivate rough cock's-foot graſs, meadow-ſweet, and ſuch coarſe plants. Graſſes which have been recommended for being remarkably grateful to cattle, as the ſheep's-feſcue graſs, or for the ſweetneſs of their foliage merely, if they are found to be deficient in the grand article of produce, will never anſwer the farmer's or grazier's purpoſe, ſince to be a good meadow it muſt be productive. Cattle, in regard to food, doubtleſs have their particular likings, though we cannot properly judge of it, in which it may be neceſſary ſometimes to indulge them; but this practice muſt not be carried too far; for as the farmer cannot afford to feed his ploughmen on pigs and poultry, neither can he indulge his cattle in general with the finer or more delicate hay or herbage. By the bye, we do not know but that the moſt productive graſſes may alſo be the moſt nutritious, or that cattle will not as eagerly eat the herbage or hay made of the meadow fox-tail graſs, as of the fine bent (*agroſtis capillaris*), and procumbent trefoil (*trifolium procumbens*). Moreover, cattle are known frequently to thrive on food to which they are habituated by neceſſity, though at firſt they could ſcarcely be prevailed on to touch it. Perſons, in making experiments, are very apt, as has been already obſerved, to conclude too haſtily from the appearance which a plant aſſumes on its being firſt planted or ſown; the moſt inſignificant vegetable will often make a great ſhow, when its fibres have freſh earth to ſhoot into;

but the trial comes when the object of our experiment has been in a meadow or paſture ſeveral years, when its fibres from long growth are matted together, and it meets with powerful neighbours to diſpute every inch of ground with it: if it then continues to be productive, it muſt have merit. We ſee that lucern, when left to itſelf, is ſoon overpowered; if we ſow broad-leaved clover, which is moſt undoubtedly a perennial, the firſt year we ſhall have a great crop of clover; let this field be left to itſelf, and the clover, like the lucern, will yearly diminiſh, not becauſe it is a biennial, as ſome have ſuppoſed, but becauſe plants hardier or more congenial to the ſoil uſurp its place: this ſhews, then, that at the ſame time that we introduce a good plant, that plant muſt alſo be a powerful one, able to keep poſſeſſion, and continue to be productive.

With regard to the ſecond quality, or that of the cattle's thriving on the food they eat; this is, undoubtedly, of great conſequence, and it is to be regretted that our knowledge of the moſt nutrient herbage is ſo limited: of thoſe plants which have been cultivated, we are able to ſpeak with ſome certainty; it is well known that clover, lucern, ſaintfoin, tares, and ſeveral other plants, have a tendency to fatten cattle; but what graſſes, or other plants, which have not been ſubjected to a ſeparate cultivation, have this particular tendency, remains to be aſcertained by experiment. But as leguminous plants, in general, are found to agree with cattle, we may reaſonably conclude that a certain quantity of them muſt be proper in paſtures. Certain paſtures are found to be more bateable or feeding than others; but whether this ariſes from ſituation, or their particular produce, remains alſo to be diſcovered by further obſervation.

Reſpecting the third quality, or the early growth of plants, as the farmers and graziers unitedly complain of the want of early herbage in the ſpring; thoſe plants, therefore, which are found to put forth early foliage, and to be grateful to cattle, are deſerving of great attention. As far as graſſes are concerned, the ſweet-ſcented vernal, the meadow fox-tail, the ſmooth and rough-ſtalked meadow-graſs, will effect all that can be expected from thoſe of Britiſh growth: much, very much, however, will depend on ſeaſons: if the winter be very ſevere, or north-eaſterly winds prevail in the ſpring, graſſy herbage will be backward: to counteract the bad effects of ſuch ſeaſons, our paſtures ſhould be warmly ſituated, not drenched with moiſture, ſheltered by thick hedges, and divided into ſmall encloſures: in ſhort, a ſet of encloſures ſhould be formed for this very purpoſe, where there is a proſpect of its anſwering the deſigns of the cultivator. But where early paſturage is the deſideratum, other plants, as well as graſſes, may deſerve a place amongſt them, as rib-wort, or rib-graſs (*plantago lanceolata*), dandelion (*leontodon taraxacum*), broad-leaved clover (*trifolium pratenſe*), with many others of the ſame kind. And as an early herbage, though it is valuable for paſturage, is no leſs ſo for hay; by the middle of May at furtheſt, a meadow of this ſort would be fit for mowing, and the ſecond hay-making might commence by the time that hay-making uſually takes place in the country. The writer has ſometimes thought, but perhaps the idea is too ſpeculative, that we ought to have two ſorts of meadows, one for hay, the other for paſture; that our hay-meadows ſhould conſiſt entirely of graſſes, and chiefly for this reaſon, that the hay would on that account be much ſooner made; an object of conſequence at all times, but more ſo when the proceſs commences in May. In June and July the more powerful heat of the ſun is able to exſiccate the thick leaves and ſtalks of the more ſucculent plants; but, in the neceſſary prolongation of this buſineſs, the graſſes muſt materially ſuffer. But for the purpoſe of paſturage, the attention of the agricultor ſhould be chiefly directed to ſuch ſorts of graſſes as have the propenſity of running to leaves, in preference to ſuch as abound more in flower-ſtalks or ſtems.

The ſame writer ſtates, that if we examine our meadows, paſtures, and downs, we ſhall find them pretty much in a ſtate of nature, and, excepting thoſe paſtures which of later years have been ſown with ray-graſs and clover, full of an indiſcriminate mixture of plants, ſome of which afford good, others bad food, ſome good crops, others ſcarcely any crops at all: but that he may not be thought to ſpeak at random on this ſubject, he will ſtate a few facts to corroborate what he has aſſerted. His worthy and much-eſteemed friend, Thomas White, eſq. with a view to aſcertain the produce of ſeveral downs and commons fed on by ſheep, procured, from each of thoſe under-mentioned in Hampſhire and Suſſex, a turf, which, though not more than ſix inches in diameter, and choſen indiſcriminately, produced, on being planted in his garden, as follows:

Different Turfs.

Turf from Selborn-Common.—Plantago lanceolata, agroſtis capillaris, avena flaveſcens, dactylis glomerata, feſtuca duriuſcula, poa annua, cynoſurus criſtatus, trifolium repens, crepis tectorum, achillea millefolium, galium verum, hypochæris radicata, hieracium piloſella, thymus ſerpyllum.

Turf from Oakhanger.—Trifolium repens, holcus lanatus, poa annua, agroſtis capillaris, agroſtis paluſtris.

Turf from Deortun.—Ranunculus repens, lolium perenne, holcus lanatus, prunella vulgaris, feſtuca duriuſcula, agroſtis paluſtris, trifolium repens, crepis tectorum, achillea millefolium.

Turf from Glynd-hill.—Medicago lupulina, achillea millefolium, poa pratenſis.

Turf from the ſame.—Avena flaveſcens, feſtuca duriuſcula, feſtuca ovina, hieracium piloſella, agroſtis capillaris, trifolium repens, thymus ſerpyllum.

Turf from Short-Heath.—Feſtuca bromoides, aira præcox, juncus campeſtris, poa annua, agroſtis capillaris.

Turf from Mount Cabron.—Rumex acetoſa, daucus carota, medicago lupulina, poterium ſanguiſorba, feſtuca duriuſcula, avena flaveſcens.

Turf from Ringmer-Down.—Linum catharticum, ſcabioſa columbaria, ornithopus perpuſillus, avena flaveſcens, feſtuca duriuſcula, trifolium repens, hypochæris radicata, crepis tectorum, lotus corniculatus, juncus campeſtris, hieracium piloſella, feſtuca ovina, thymus ſerpyllum, poa pratenſis.

It is, perhaps, no ſmall recommendation to the *poa trivialis*, that it is a principal graſs in that uncommonly productive meadow near Saliſbury, mentioned by Stillingfleet, and more particularly deſcribed in the firſt volume of the Memoirs of the Bath Agricultural Society. And that the account given of the extraordinary fertility of this meadow excited his curioſity, and induced him to requeſt a gentleman reſiding near the ſpot to favour him with ſix ſmall turfs, cut up in different parts of the ſaid meadow, and which being planted in his garden, at Lambeth-Marſh, produced as follows:

Different Turfs.

Turf 1.—Poa trivialis, ranunculus acris, triticum repens, agroſtis paluſtris.

Turf 2.—Poa trivialis, alopecurus pratenſis, triticum repens.

Turf 3.—Poa trivialis, agroſtis paluſtris.

Turf 4.—Poa trivialis, triticum repens, peucedanum ſilaus.

Turf 5.—Poa trivialis, alopecurus pratenſis, agroſtis paluſtris, avena elatior, triticum repens.

This experiment proves, in a great degree at leaſt, what he long before ſuſpected, that the extraordinary fertility of this meadow aroſe not from any new graſs peculiar to it, but from ſeveral unuſual circumſtances concurring and favouring in an uncommon degree the growth of certain well-known graſſes, eſpecially the poa trivialis and agroſtis paluſtris; conſequently, in the forming and improving of graſs-lands, the moſt certain plan will be to cultivate the ſeeds of ſuch graſſes as may be moſt adapted to them, and afterwards ſow them at proper ſeaſons upon the lands, when they have been put into a ſuitable condition for their reception.

The directions given are, that if a piece of ground can be had that is neither very moiſt nor very dry, it will anſwer for all the ſeeds; they may then be ſown on one ſpot: but if ſuch a piece cannot be obtained, they muſt be ſown on ſeparate ſpots, according to their reſpective qualities, no matter whether in a garden, a nurſery, or a field, provided it be well ſecured and clean. Dig up the ground, level, and rake it; then ſow each kind of ſeeds thinly in a ſeparate row, each row nine or twelve inches apart, and cover them over lightly with the earth; the latter end of Auguſt or beginning of September will be the moſt proper time for this buſineſs. If the weather be not uncommonly dry, the ſeeds will quickly vegetate; and the only attention they will require will be to be carefully weeded: in about a fortnight from their coming up, ſuch of the plants as grow thickly together may be thinned, and thoſe which are taken up tranſplanted, ſo as to make more rows of the ſame graſs. If the winter ſhould be very ſevere, though natives, as ſeedlings, they may receive injury; therefore it will not be amiſs to protect them with mats, fern, or by ſome other contrivance. Advantage ſhould alſo be taken of the firſt dry weather in the ſpring, to roll or tread them down, in order to faſten their roots in the earth, which the froſt generally looſens; care muſt ſtill be taken to keep them perfectly clear from weeds. As the ſpring advances, many of them will throw up their flowering ſtems, and ſome of them will continue to do ſo all the ſummer. As the ſeed in each ſpike or panicle ripens, it muſt be very carefully gathered, and ſown in the autumn, at which time the roots of the original plants, which will now bear ſeparating, ſhould be divided and tranſplanted, ſo as to form more rows: the roots of the ſmooth-ſtalked meadow-graſs in particular, creeping like couch-graſs, may readily be increaſed in this way; and thus, by degrees, a large plantation of theſe graſſes may be formed, and much ſeed collected for the uſe of the agricultor. But a more ready way, according to a late writer, is, for the farmer to notice that ſpecies of graſs moſt affected by his ſoil, and carefully to gather the ſeed from a piece of old meadow, purpoſely left three or four weeks longer than common, or at leaſt long enough to become ſufficiently ripe. He ſhould not ſcruple the trouble of ſelecting the heads as they lie in the ſwath; but they who deſire not to be ſo particular, will threſh out the ſeed together, either in the field or before it ſhall have heated in the mow. And good ſeeds of different ſorts of graſſes may now alſo be procured from different ſeedſmen in large towns and other places; but the collection ſold under the title of hay-ſeeds ſhould never be truſted to in any reſpect. Mr. Curtis, from the numerous applications that were made to him by gentlemen for graſs-ſeeds, was induced to ſelect ſuch as appeared to him the moſt uſeful, and thereby rendered the public an eſſential ſervice. He wiſhed at leaſt to put it in their power to decide on a matter which had been long agitated, and from which he was far from being the only one that entertained the ſanguine hopes of its proving a great national advantage. The graſſes he has recommended will, he is confident, do all that our natural graſſes can do: they are ſix of thoſe which conſtitute the bulk of our beſt paſtures; moſt of them are early, all of them are productive, and they are adapted to ſuch ſoils and ſituations as are proper for meadows and paſtures. But, let no one expect them to perform wonders; for after all they are but graſſes, and as ſuch are liable to produce great or ſmall crops, according to particular ſeaſons, or to the fertility or barrenneſs of the ſoil on which they are ſown and cultivated.

This liſt comprehends the *anthoxanthum odoratum,* or ſweet-ſcented vernal-graſs; the *alopecurus pratenſis,* or meadow fox-tail graſs; the *poa pratenſis,* or ſmooth-ſtalked meadow graſs; the *poa trivialis,* or rough-ſtalked meadow graſs; the *feſtuca pratenſis,* or meadow-feſcue graſs; and the *cynoſurus criſtatus,* or creſted dog's-tail graſs; of which repreſentations may be ſeen at *figs,* 1, 2, 3, in *Plate, Graſſes, Agriculture,* and *figs.* 1, 2, 3, in *Plate Graſſes*; but more full accounts of them may be found by referring to their different botanical titles, in different parts of the work.

But of the above graſſes, the meadow fox-tail and rough-ſtalked meadow graſs are fitteſt for moiſt land; the meadow-feſcue, or ſweet-ſcented vernal, are the moſt proper for land either moiſt or moderately dry; and the ſmooth-ſtalked meadow-graſs and creſted dog's-tail are thoſe that are beſt ſuited for dry paſtures and other ſimilar lands.

It is, however, ſuppoſed, that in the more ſouthern parts of the kingdom we may in vain expect to clothe dry ſoils with the conſtant verdure of graſſes; they will not ſtand the drought of hot parching ſummers: in ſuch ſeaſons, they are only plants which ſend down roots to a great depth that can be expected to look green or be productive, as the *lotus corniculatus, medicago falcata,* and ſome others.

The order of flowering in the above graſſes is: 1. Sweet-ſcented vernal. 2. Meadow fox-tail. 3. Smooth-ſtalked meadow. 4. Rough-ſtalked meadow. 5. Meadow-feſcue. 6. Creſted dog's-tail.

It is obſerved that many more graſſes might be added to this liſt, and thoſe too which perhaps might be highly deſerving of it; but he has his doubts, whether by recommending more he might not increaſe the difficulty of introducing graſs-ſeeds without any adequate advantage in return.

But beſides theſe, the *feſtuca ovina,* or ſheep's-feſcue-graſs; the *feſtuca duriuſcula,* or hard-feſcue graſs; the *poa compreſſa,* or flat-meadow graſs; the *poa paluſtris,* or marſh-meadow graſs; the *phleum nodoſum,* or knot-graſs; and the *lolium perenne,* or rye-graſs, which is an uſeful graſs in many caſes; may all be employed with advantage. They may be ſeen at *figs.* 1, 2, 3, in *Plate Graſſes,* and at *figs.* 1, 2, 3, in *Plate Graſſes.*

And in the ſecond volume of his Eſſays on Rural Affairs, Dr. Anderſon has likewiſe given deſcriptions of many others, which, he conceives, may be beneficially employed in forming graſs-lands, ſuch as the *alopecurus bulboſus,* or bulbous fox-tail graſs; the *feſtuca rubra,* or purple feſcue-graſs; the *holcus mollis,* or creeping ſoft graſs; the *plantago anguſtifolia* and *tenuifolia,* or narrow-leaved and ſmall graſs-leaved plantain or rib-graſs; and the *poa procumbens,* or creeping-meadow graſs.

In a valuable "Eſſay on the Converſion of Graſs-Land into Tillage," inſerted in the Communications to the Board of Agriculture, vol. iii. part 1. the following detail of ſeveral plants of the graſs kind is given, with the ſoils they are moſt proper for, or on which they ſucceed to the greateſt advantage.

“ Ray-graſs *(lolium perenne)*. This graſs, which for many purpoſes is a very valuable one, is chiefly to be recommended for the two diviſions of ſoil diſtinguiſhed under the titles of loam and ſand. It will flouriſh on any land, except ſtiff clay, and will grow even on that; but, upon rich ſands and loams, it becomes not only a good ſpring-graſs, but, if properly managed by due mixtures, turns out well as a permanent paſture-land; always, however, moſt valuable by being ſheep-fed, for which it is ſingularly adapted. Mr. Peacey's two varieties of it are ſaid, by ſome perſons who have tried them, to be ſuperior to the common ſort. Mr. Profeſſor Martyn, he ſays, ſtates the *cynoſurus cæruleus, poa nemoralis, bromus mollis, alopecurus, anthoxanthum,* and *poa pratenſis,* as all being earlier than the *lolium perenne,* or ray.” See LOLIUM *Perenne.*

“ Yorkſhire white *(holcus lanatus)*. This, he obſerves, flouriſhes well on any moiſt ſoil, and grows very generally, except on the moſt dry and barren ones, where, however, it is alſo found. It ſhould be ſown chiefly with a view to ſheep, for it is not equally good for other ſtock: many acres of it have been cultivated on his farm for ſheep, and it has anſwered greatly when kept cloſe fed. Mr. Marſhall, in his Midland Counties, mentions it as a good graſs for cows and other cattle, but bad for horſes. In his York Economy he, however, condemns it in toto; probably from not then having ſo cloſely remarked its qualities.” See HOLCUS *Lanatus.*

“ Meadow-feſcue *(feſtuca pratenſis)*. This is an excellent graſs for good loams and clayey ſoils, and he has found it abound largely on dry loams. He has laid down ſome parts of fields with it for compariſon with other graſſes on wet ſandy loams on a clay marle bottom, worth 14*s.* or 15*s.* an acre; but has found it giving way in four years to the plants more indigenous to the ſoil. He does not think there is any better graſs for either hay or paſturage, and it yields ſeed in great abundance. He adds, that colonel St. Leger was, he believes, the firſt who entered largely into the culture of this graſs: and Mr. Majendie, of Eſſex, revived it, and began with the *alopecurus*.” See FESTUCA *Pratenſis.*

“ Meadow fox-tail *(alopecurus pratenſis)*. He thinks that for moiſt loams and clays, there cannot be a better graſs than this: it is very early, and it abides on his farm after nine or ten years on the ſoils upon which the meadow-feſcue gives way to others. It has alſo been found, by Mr. Majendie, hardier againſt froſts than the *poa trivialis:* the greateſt objection to it is the difficulty of getting the ſeed in any degree of plenty; there is an inſect that feeds on it, and occaſions much diſappointment. Mr. Profeſſor Martyn, in his excellent “ Flora Ruſtica,” ſpeaks, he obſerves, highly of this graſs, and ſays the ſeeds may be collected without much difficulty; but he does not there advert to the inſect which is ſo pernicious, as noticed by Mr. Majendie, and by the ingenious Mr. Swayne, in his “ Gramina Paſcua.” In a field on his farm, where it is very well eſtabliſhed, and the herbage thick, it produces very few ſeed-ſtalks.” See ALOPECURUS *Pratenſis.*

“ Creſted dog's-tail graſs *(cynoſurus criſtatus)*. It is remarked, that to judge from the appearance of the bents of this graſs in poor upland but moiſt paſtures, a man would think it a very unpromiſing plant; but the rich marſhes of Bridgewater and Boſton, the famous paſturages of Painton in Devonſhire, and thoſe cloſe to Mr. Buller's caſtle near Leſkeard in Cornwall, Mr. Thorne's bullock-grounds on a limeſtone bottom near Taviſtock; Mrs Williams's at Little Malvern in Worceſterſhire, (which are among the richeſt paſtures in the kingdom), all abound, he aſſerts, very greatly in this graſs; in ſome of them it is the predominant herbage. Mr. Marſhall, in his York Economy, places it as the moſt prevailing plant in the beſt graſs-meadows of the vale of Pickering, ſome of which will feed a large cow from May-day to Michaelmas. Very fortunately it abounds much with ſeed, ſo that he has had many buſhels gathered in a ſeaſon by poor women and children, at one ſhilling a pound, and laid down many acres with it ſucceſsfully. Attention ſhould be paid to its being ripe; for he once ordered eight buſhels to be ſown on eight acres, and it failed from deficiency in ripeneſs.” See CYNOSURUS *Criſtatus.*

“ Roughed-ſtalked meadow-graſs *(poa trivialis)*. It is obſerved that Mr. Boys, of Betſhanger, in Kent, has been the largeſt cultivator of this graſs in the kingdom, and ſold large quantities of the ſeed, but gave it up for want of a demand. It is, he aſſerts, an excellent graſs on good, ſound, and moiſt loams. It is accounted in Lombardy ‘ the queen of meadow plants *(la regina dell' erbe)*,’ whether for dry paſtures or water meadows; multiplying itſelf much by ſeed, and little by the root; ſo that, if attention be not paid to permit ſome ſeed to fall, its quantity will ſenſibly diminiſh. Excellent for all ſorts of cattle.”

“ This hint concerning the ſeed is worth attention in England. Major Cartwright has found the *poa pratenſis* to be an excellent graſs on rich loams; and both ſucceeded well with ſir William Clayton, of Harleyford.” See POA *Trivialis.*

“ Cock's-foot *(dactylis glomerata)*. This graſs has been largely cultivated over the farm he now manages, and to his ſatisfaction on wet loams on a clay marle bottom, upon which the finer graſſes are apt to give way in a few years to the indigenous produce. If ſuffered to riſe high, it is very coarſe; but, fed cloſe, is a very valuable ſheep-paſture. Women and children make good earnings in gathering it at 4*s.* a buſhel. He has ſown two buſhels an acre, and 10lbs. common red clover; and when the clover wears out, the graſs fills the land, and abides well in it. It grows well in winter. It has been found highly uſeful as an early ſheep feed.”

It is ſtated in the Norfolk Report on Agriculture, that “ ſir Mordaunt Martin, in 1788, obſerving, by an experiment, that this graſs grew four inches in leſs than three days, determined to attend more particularly to it: he remarked, that when ſheep were let out of a fold, they ran over every thing, to get at a baulk that was full of it, and there ate it in preference to other graſſes. In ſome parts of Norfolk it is called cows' graſs, from their being very fond of it. He began to cultivate it in 1794. It grows at Midſummer, in a drought, when every thing elſe is burnt up. He ſows it with nonſuch, inſtead of ray-graſs, and finds it much more profitable.” And “ Mr. Overman, alſo, obſerving the eagerneſs with which ſheep, when let into a field at Burnham-market that had ſome cock's-foot graſs in it, ran over ray-graſs, and every thing elſe, to get a bite of this plant, thought it worth cultivating, and ſowed about an acre, on the dry gravelly part of his farm, juſt above the marſh. This ſpot was the only one, in a large field, that did not burn in the ſevere drought of 1800, and convinced him of the excellence of the graſs.” He alſo ſhewed the writer “ a beautiful crop of drilled wheat, which could ſcarcely be eſtimated at leſs than four quarters and a half per acre, pointed out a part of the field, ſuperior, if any thing, to the reſt; and ſaid it was an experiment on the cock's-foot graſs; he had found it an excellent plant for ſheep, but having examined the roots, perceived them to be ſo ſtrong, that he had ſome ſuſpicion they might exhauſt the land, and therefore ſowed this piece for a trial: the reſult has ſatisfied him that all apprehenſion of the kind was ill-founded, and he intends ſubſtituting it for ray-graſs." The author has alſo "cultivated this graſs on a large ſcale for many years, and has found it of great uſe. It is a moſt valuable plant when kept cloſe fed." See DACTYLIS *Glomerata*.

"Tall oat-graſs *(avena elatior)*. This is another coarſe graſs, profitable when kept cloſe fed: the ſeed might be had in any quantity from France, or gathered by hand in England. In the Rev. Mr. Swayne's experiment, it yielded a greater weight than any other graſs." See AVENA *Elatior*.

"Timothy graſs *(phleum pratenſe)*. This graſs is repreſented by all travellers in America, he obſerves, as the great ſupport of cattle, &c. wherever meadows are found; and it is aſſerted to have conſiderable merit. He has ſeveral times made the trial of keeping it cloſe fed by ſheep on a moiſt loam, upon a clay marle bottom. The ſucceſs was very encouraging; enough, he thinks, to prove that it is an object, in this line of huſbandry, which merits conſiderable attention; and the more, as the ſeeds are to be had, very clean dreſſed, in any quantity from America, at about a guinea a buſhel; which is ſufficient, with other plants, for four or five acres of land. He believes it is beſt adapted to clay, moiſt loams, and eſpecially peat." See PHLEUM *Pratenſe*.

"Yarrow *(achillæa millefolium)*. This, he aſſerts, is one of the moſt common and moſt valuable plants that is to be met with in England. On his farm the cultivation of it has been carried on with ſucceſs as a ſheep-paſture for ſome years. It is found on moiſt loams almoſt equally with dry burning ſands, gravels, and chalks. It has a ſingular quality of reſiſting drought on the moſt arid ſoils; ſo that, if you ſee at a diſtance a green ſpot on a burnt-up, cloſe-fed paſture, twenty to one but it is clothed with this plant. It is found in the richeſt meadows and bullock-paſtures. Five ſhillings per buſhel are given for gathering the ſeed in October: it is a plant deſerving great attention. Sheep are very fond of it. It is ſaid to form a fourth-part of the herbage of ſome of the fine meadows of Lombardy."

"Burnet *(poterium ſanguiſorba)*. It is remarked that there are large tracts of the fineſt parts of the South Downs upon which this plant forms half the indigenous paſturage. It abounds much alſo on all other chalk downs; but it will flouriſh on any ſoil, on ſand, clay, peat, &c. Some writers ſpeak of it for cows: it has been cultivated on his farm theſe five and twenty years for ſheep, for which animal it is very uſeful. The ſeed is to be bought almoſt every where." See BURNET.

And it is obſerved in the Agricultural Survey of Norfolk, that this plant was "introduced at Stoke 35 years ago, as the writer then regiſtered, with great ſucceſs; but it never made any progreſs, though it yielded luxuriant food for many horſes in February." However, "the reputation of this plant attracted the notice of Mr. Coke, who formed an experiment at Holkham, to examine carefully its merits, and, with the ſpirit that characterizes his huſbandry, ſowed 40 acres, mixing a ſmall quantity of white clover and rib-graſs with it. The reſult was as deciſive as can be imagined; the field has been fully and inceſſantly ſtocked with ſheep, and was conſtantly pared as cloſe to the ground, as a favourite ſpot in a paſture is by horſes." And in other reſpects it is alſo valuable, as "Mr Bevan has found it to be the moſt wholeſome food for ſheep in a wet ſpring, and a certain remedy for the flux." And he "is never without twenty acres of it."

"White clover *(trifolium repens)*. It is aſſerted that this plant has hitherto been the main dependence of thoſe who have laid down land to graſs; and though, for ſheep, it has not the ſweetneſs of ſome other plants, or of red clover, yet upon the whole, it is one of the beſt that can be relied on for all rich or dry loams, ſands, &c. and alſo for rich and drained clays and peats; but on poor wet loams and clays it will not abide, but gives way to the water-graſs *(agroſtis ſtolonifera)* and noxious plants, or other indigenous graſſes. There is no better teſt of good land, than its running ſpontaneouſly to this plant; from the fine loams on rock, upon the Tamar, to the deep friable ones of Leiceſterſhire, red-clover, left unploughed, gives way to a thick covering of this plant. Whatever ſeeds be ſown, this clover ſhould form a part of the dependence for ſucceſs. Mr. Bakewell, Mr. Wright of Norfolk, and ſeveral other practical farmers, made this obſervation, that ſtock has been known to do badly, though there was much food on the ground; perhaps that is preciſely the reaſon; and that this plant, like ſo many others, demands very cloſe feeding to diſcover its merit." See CLOVER.

"Trefoil *(medicago lupulina)*. It is obſerved that, though only a biennial, it is ſure to ſhed ſo much ſeed that it rarely wears out of land. It is a good plant, not at all nice in ſoil, and the ſeed cheap." See TREFOIL.

"Cow-graſs *(trifolium medium)*. An excellent plant for clays and ſtrong loams. It is ſaid, in the Lincoln Report, that Mr. Ancel got good crops on a rabbit ſand; the hint is worth purſuing, but he has not ſeen it cultivated on ſuch ſoils. It is much more abiding than common clover. The ſeed is always to be had: it is known alſo under the name of marle graſs. Mr. Bakewell's method of laying down was, by common red clover and ray graſs, being ſure of plenty of white clover and good graſſes coming: but he prepared by two crops of turnips in ſucceſſion, and ſowed with the barley following. On ſuch land as his, the practice is not to be condemned, but on other ſoils it would fail entirely."

"Rib-graſs *(plantago lanceolata)*. It is aſſerted that upon rich ſands and loams this plant gives a conſiderable herbage, and on poorer and drier ſoils it does well for ſheep; but that it is inferior to ſome others. Mr. Marſhall obſerves, that it has ſtood the teſt of years' eſtabliſhed practice in Yorkſhire, and is in good eſtimation; though not well affected by horſes, and bad for hay, from retaining its ſap. The eminent Haller informs us, that the aſtoniſhing richneſs of the famous dairies of the Alps, deſcribed by Scheuchzer, is attributed entirely to the plenty of this plant, and the *alchemilla vulgaris*. The ſeed is always plentiful." See PLANTAGO.

"Lucern *(medicago ſativa)*. This is more confined than any of the other plants. A landlord ſhould, he thinks, only ſtipulate for it on very rich, deep, friable, dry, ſound, mellow loams, and fertile ſands, worth 30*s*. an acre. Upon ſuch lands, he cannot do better than to encourage it among the tenantry, to be ſown broad-caſt, 20lbs. an acre, and to remain while productive, which will be from twelve to fifteen years. On ſuch ſoils it will, he ſays, ſupport more cattle than any other plant." See LUCERN.

But more full accounts of theſe graſſes will be found under the different heads which are referred to.

With reſpect to *hay-ſeeds*, it is ſtated that the only caſe in which theſe are admiſſible is, when a perſon has a very clean and valuable meadow or paſture which he ſaves with a view for ſeed; drawing out the bad plants whilſt the crop is on the ſwath, and threſhing the produce on a cloth, after ſtanding till the ſeeds be ripe. Thus managed, excellent ſeed may be procured with eaſe, and be beneficially employed in the forming of graſs-lands.

In regard to the arrangement of theſe different graſſes, as they relate to, or are proper for different ſorts of ſoil, it is fully ſhewn in ſpeaking of the methods of bringing land into the ſtate of graſs or ſward. See *Laying* LAND *down to Graſs*.

But beſides the plants that have been noticed above, it "is remarked that there are many others, ſome of which have been tried under his direction, which deſerve much attention; but he has not named them in the above-mentioned liſt, becauſe the ſeed cannot be procured but with difficulty: ſome perennial vetches, clovers, melilots, lotuſes, &c. &c. And ſeveral others are highly ſpoken of by ſome writers; yet as his own trials have not been equally ſucceſsful, he is not authoriſed to recommend them. He never tried the *vicia ſepium* ſufficiently, to give an opinion of it; but, by Mr. Swayne's account, it deſerves much attention."

However, in conſidering the modes of laying lands to the ſtate of ſward, liſts containing the proportions or quantities of different ſorts of graſs-ſeeds ſuitable for different ſorts of land, are offered to the attention of the cultivator. See *Laying* LAND *down to Graſs*.

It is remarked in a general way by the ſame writer "that if the land laid to graſs be intended for ſheep, it is not an object of very great conſequence to ſow only the finer graſſes; as cloſe feeding after the firſt year will make any graſs named in the liſts fine, ſweet, and productive; but this effect depends altogether on its being conſtantly fed cloſe, that is, all ſeed-ſtems being prevented from riſing. Every good farmer is ſenſible of the neceſſity of this with ray-graſs, but moſt unaccountably does not extend a ſimilar concern to other graſſes. Above 200 acres under the author's management have been laid down to graſs, chiefly for ſheep; and he has ſtocked the fields ſo early in ſpring, and ſo thickly, as juſt to keep down the ſeed-ſtems: the cock's-foot, oat graſs, and Yorkſhire white, with this management, have proved ſweet feeding graſſes, not at all rejected, even in fields where the flock had a choice. Several writers ſeem to have been very ſenſible of the conſequence of cloſe feeding. Mr. Davis, in the Wiltſhire Report, ſays, "the ſweetneſs of the ſeeds on the downs of Wilts depends much more on its being kept cloſe, and eaten as faſt as it ſhoots, than on any particular good quality of the graſs itſelf; for there are many downs that, when cloſe fed, appear to be a very ſweet paſture, but which, if ſuffered to run a year or two without a full ſtock on them, will become ſo coarſe, that ſheep will almoſt as ſoon ſtarve as eat the graſs."

And in the Survey of the County of Stirling in Scotland, it is ſtated, that, upon Benlomond, &c. the paſturing of ſheep has evidently, in the courſe of twenty years paſt, improved the quality of the herbage ſo as to raiſe graſs of a good ſpecies, and in very conſiderable abundance, where nothing formerly prevailed but bad kinds of graſs, and theſe in no great plenty: and the practice bids fair to baniſh heath from all the places that are paſtured by ſheep."

Further, Liſle, who was the beſt writer on huſbandry we had for many ages, alſo remarks, "that there are poor ſoils which require a much longer time to grow a ſecond inch than the firſt, and that conſequently on ſuch it is much more profitable to keep ſheep than cattle." The writer, on firſt reading this paſſage, made the experiment on land of 12*s.* and 15*s.* an acre, clipping the plants with ſciſſars, and carefully meaſuring and weighing the produce, and comparing it with neighbouring plants left to perfect the ſeed-ſtem; the ſuperiority was proportioned to the times of cutting. Sheep-feeding not only, he ſays, ameliorates, by enriching the ſoil and fining the herbage, but alſo by deſtroying weeds. Ragwort, with which the bullock-grounds of Limerick, in Ireland, are overrun for want of ſheep is, it is obſerved, much affected by them: and Mr. Marſhall, in his York Economy, gives an inſtance of a meadow, foul in the extreme with knobweed, cured by paſturing it repeatedly in the ſpring with ſheep. But here, a counter remark muſt be made, which is, that after a field has been paſtured long with ſheep, and cloſe fed, it becomes unable to yield a growth of hay: the plants, by being conſtantly cropped down, acquire a dwarfiſh habit, however quick the growth in that early ſtage. There is a ſmall field on the eſtate which he manages, which has been under graſs, time immemorial, and kept fed for the laſt forty years at leaſt, except one year in which it was mown, expecting a vaſt crop: the ſeaſon was very favourable, but he was utterly diſappointed, for the produce was ſmall. He has known the ſame thing happen on incloſing an old common. In Scotland a ſimilar remark has been made by Mr. Wight. "Two incloſures of the ſame ſoil were laid down together with graſs-ſeeds of the ſame kind: after two years' hay, the one was ſurrendered to paſture; from the other a crop of hay was taken every other year. After ſeven years' abſence, the proprietor returned home, and wanting more hay, mowed both, and that which had been paſtured gave the worſt crop." Something like the ſame thing has been obſerved in Switzerland, as ſtated in the Tranſactions of the Berne Society. It has occurred alſo in other inſtances.

With regard to the forming of graſs or ſward, the procuring of good ſeed has been found, from long experience in every part of the kingdom, to be of all other works the worſt executed by tenants: they ſow the cheapeſt ſeeds which can be procured, that is, common clover or ray, or the rubbiſh of their hay-lofts: the clover gives a crop the firſt year; but, as it wears out, all ſorts of trumpery ſucceed, if the ſoil be not good enough to run ſpontaneouſly to white clover. Great care ſhould therefore be taken by the owners of lands, which are to be brought into a ſtate of graſs, to have proper ſorts of graſs-ſeeds provided. About 25*s.* will purchaſe the ſeeds in moſt inſtances: the expence may be reckoned from 20*s.* to 30*s.* per acre; but depending on various circumſtances, as the ſtate of markets, and the price of labour. Of the ſeeds recommended, the following are to be bought in any quantity: cow-graſs, Yorkſhire white, Timothy from America, white clover, trefoil, ray, burnet, rib. And dog's-tail and cock's-foot are eaſily gathered by hand. Moſt of the graſs-ſeeds that have been recommended as uſeful in forming good graſs-lands may indeed, now, we believe, be had of the different ſeedſmen in London, and other places, as already noticed.

And the beſt methods of preparing the land, ſowing the ſeeds, and managing the new graſs-lands, are conſidered in treating of the practice of reſtoring arable lands to graſs. See *Laying* LAND *down to Graſs*.

GRASS, *Artificial*, a term ſignifying that kind of graſs that is produced by the ſowing of the ſeeds of different ſorts of plants that have a quick and luxuriant growth on arable land; as thoſe of the *red* or *broad clover*, *ſaintfoin*, *lucern*, *trefoil*, *tare*, *rye*, *graſs*, and other ſimilar kinds. They are ſhewn at *figs.* 1, 2, 3, in *Plate Graſſes* and at *figs.* 1, 2, 3, in *Plate Graſſes*, in *Agriculture*.

There are likewiſe ſeveral other plants of this nature, that may in all probability be employed with great advantage in the ſame intention. And it has been ſtated by a late practical writer, that "though the chief hinge on which modern huſbandry has been made to turn is that of the introduction of theſe ſorts of graſſes, it is extraordinary that they have yet, in but few diſtricts, been made to conſtitute a part of the courſe of cropping on arable land. In all well cultivated diſtricts, they, however, form a conſiderable proportion of the crops. The firſt of the above is a moſt invaluable plant, whether it be mown and uſed green, paſtured, or made into hay. By its long tap-roots it reſiſts the effect of exceſſive drought on the dryeſt ſoils, and increaſes the quantity of vegetable mould in all. It will grow on moſt ſoils, but is not equally productive; and whether it be mown and uſed in the green ſtate, paſtured, or made into hay, it generally produces four or five times the quantity of fodder that the ſame land would have done with common graſſes. Further, in good rotations, it frequently makes the ſecond crop, in lieu of white corn mown once, and the after-graſs eaten off with horſes, beaſts, or ſheep, and the land ſown with wheat. In that caſe, two pecks of the beſt ray-graſs, mixed with fourteen pounds of the clover-ſeed, ſhould be ſown upon an acre, which not only increaſes the quantity, but alſo greatly improves the quality of the hay. If the clover is for ſtall-feeding, the ray-graſs ſhould be omitted. But in poor light ſoils, the better way is to take two or three crops of corn, and then to lay the land down to reſt, three, four, five, or ſix years. In this caſe, it is adviſed that the farmer ſhould ſow the following ſeeds, in theſe proportions per acre:

Names of Seeds.	Quantities.
Of Burnet - - -	4 pounds
— Cow red-clover -	4 ditto
— White clover - -	8 ditto
— Trefoil - - -	4 ditto
— Ray-graſs - - -	2 pecks
— Vernal graſs - -	¼ ditto
— Sheep's-feſcue graſs -	½ ditto
— Creſted dog's-tail graſs -	¼ ditto.

"It is ſuppoſed, that by this management, the ſoil would acquire a vaſt increaſe of vegetable mould, and, by the paſture maintaining one-fourth more ſtock than it did before, it would be greatly charged with manure; by which means the land would be kept in perpetual good condition: and, when brought under tillage, produce one-fourth more corn than it did under other circumſtances." And it is remarked, in the Norfolk Survey, that "Mr. Purdis, of Eggmore, was recommended by a friend, whoſe management he had ſeen and approved, to ſow his ſeeds at twice: half of each ſort (white and red clover, and ray) at the time of ſowing barley; and the other half before the rollers in going over the young crop: and this practice he intends to purſue in future. He thinks it will give them a better chance of ſucceeding. He has 600 acres of ſeeds: he ſows the great quantity of 14lb. an acre of white clover, 8lb. of red, and one buſhel of ray-graſs. The laſt he eſteems much in ſpring; and, when an obſervation was made againſt it, ſaid, that in April and May he had three thouſand ſheep that found the excellence of it." This ſhould be attended to by the farmer. It is alſo further ſtated, that, "in 1784, in regiſtering the huſbandry of that ſpirited cultivator of Holkham, it was remarked, that 'thoſe who have been converſant in the huſbandry of old improved countries, know that a common complaint is the failure of red-clover. It has been ſown ſo repeatedly, that the land is ſaid to be ſurfeited with it. In the ſame diſtrict it comes to nothing on the old improved lands, yet yields immenſe crops on any accidental ſpot, where never, or rarely, ſown before.' The obſervation is ſo common, that no doubt can remain of the fact; however, it may be attributed to certain methods in management purſued in this county. Peas and tares had been tried as ſubſtitutes, but they are tillage-crops, and what theſe thin ſoils, haraſſed with the plough, want, is reſt. Mr. Coke, it is added, turned his views to a different and better quarter, to other artificial graſſes, which would anſwer the ſame purpoſe as clover and ray-graſs. He had recommended to him, on a former occaſion, trefoil, white clover, cow-graſs, rib-graſs, and burnet. Mr. Coke applied them with no inconſiderable ſagacity to the preſent purpoſe, and, that the experiment might not be deluſive, tried them ſpiritedly upon 30 acres in the middle of a large piece, laid with clover and ray-graſs. The quantities of ſeed he has found will vary according to circumſtances; but, in general,

Names of Seeds.	Quantities.
Of Cow-graſs - -	8 to 10lb.
— White clover - -	5 to 8lb.
— Rib - - -	5 to 8lb.
— Burnet - -	5 to 12lb.
— Trefoil - -	5 to 8lb.

according to the price, and alſo the intended duration of the lay. The ſucceſs of the firſt trial induced him to lay down a yet larger ſpace the ſecond year. And the third (with the barley of the laſt ſpring), no fewer than 221 acres; this is, in truth, ſays the writer, doing juſtice to a new huſbandry. Mr. Coke has found that thoſe ſeeds fill the land completely with plants, which are abiding two and even three years: and how much longer they may laſt, is more than he can pronounce, as their appearance is yet as good as ever. The author rode over all the pieces, and never ſaw a finer or more regular plant than they exhibited. And he has, on ſeveral occaſions, remarked, that ſheep give a preference to theſe graſſes, whenever ſown in the ſame field with clover and ray-graſs." And it is added, that "in regard to the continuance of theſe trials, ſome of the paſtures now remain, and are as fine as the ſoil will yield: thick, clean, and ſweet." And it is here remarked in regard to land being tired of this plant, that the obſervation he made, "during nine years that he was in the conſtant habit of viewing the farm of Mr. Arbuthnot, in Surrey, merits ſome attention. When he began to farm, the land was ſick of clover, inſomuch, that it was almoſt ſure to fail, from having been, perhaps for a century, ſown every four or five years. His friend adopted the courſe of—1. Beans; 2. Wheat; 3. Clover, in which it occurred once in three years, and the farmers predicted an abſolute failure: he viewed three courſes, and better crops, of pure red clover, were never gained. He began with ploughing treble the depth of that to which the land had been uſually ſtirred, and he manured very amply for every crop of beans, partly with night-ſoil, from London. In what degree the ſucceſs aroſe from depth of tillage, and what degree from a variation in manuring, cannot be aſcertained; but the experiment proved that theſe agents were equal to the cure of the malady." It is alſo further noticed, that "ſome farmers in Norfolk have moved out of the common ſphere, and ventured to plough deeper than their predeceſſors; nor have they found any inconvenience in ſo doing. It merits conſideration, whether this practice will not prove in ſome meaſure a remedy to the failure of clover. As to manuring, and eſpecially in great variations, the means are generally limited, and a change in this reſpect, however deſirable, is rarely in their power." But, "the only effective remedy hitherto practiſed, is that of omitting clover altogether, for one or two rounds, which points out the great importance of introducing as many new artificial graſſes as poſſible." See *Red* CLOVER.

The red-cow clover is another plant of the clover kind, which has been found very uſeful as an artificial graſs. According to Mr. Amos it is perennial, and grows naturally in high chalky fields, and in gravelly fields with clay beneath. In the moſt improved part of the country, when the land is to reſt for ſome years, this ſeed is ſown along with the white clover, as it continues in the ground much longer than the meadow-trefoil, and is nearly as productive, eſpecially on chalky and poor ſorts of land. And that where a crop of any of thoſe clovers is taken in lieu of a crop of corn, the grain ſhould be ſown firſt, but leſs in quantity than if no ſeeds were ſown with it; and, after the land has been made fine by harrowing and rolling them, fourteen pounds of clover-ſeed, and two pecks of beſt ray-graſs, ſhould be ſown upon an acre buſh-harrowed the length-way, and rolled the croſs way of the ridges: afterwards the whole muſt be well gripped or drained. Nothing more is neceſſary to be done, on account of the ſeeds, till the next ſpring, when the land ſhould be well dreſſed with the ſward-dreſſer or harrows, drawn with long buſhy thorns, the latter end of March, or the beginning of April; then cleaned and rolled the croſs way again. In all theſe operations, the land ſhould be neither too wet nor too dry, but in a due medium with reſpect to both theſe extremes, as, under other circumſtances, they do not ſucceed ſo well.

The time for cutting thoſe two graſſes is, when they are in full flower, and rather ſhewing evidences of declining or paſſing their maturity. See Clover.

And the white clover is, in Mr. Amos's opinion, the ſweeteſt graſs for all ſorts of ſtock yet known, and makes the cloſeſt ſward, and is very productive of foliage. Hence it is, he conceives it moſt peculiarly adapted to laying down land to paſture. It flouriſhes moſt upon rich, dry, warm ſoils; yet it will accommodate itſelf to moſt kinds. It is ſeldom ſown alone, unleſs it be to raiſe the ſeed; nor ſhould it ever be mown for hay. In laying down rich ſoils, which are intended to remain in paſture for many years, this ſeed ſhould predominate in the compoſition that is made uſe of. But in the Agricultural Report of Norfolk it is ſtated, that "Mr. Wright, of Stanhow, does not like white clover; he thinks it a bitter food, and that ſheep do not eat it kindly; ſo that while much food ſeems to be on the ground, ſtock do badly. This is an uncommon opinion, but the writer remembers Mr. Bakewell ſtarting the ſame idea." See *White* Clover.

The procumbent or hop-trefoil, is another plant of this ſort, which is not very productive, and thrives beſt upon dryiſh gravelly fields, and paſtures which have the ſame nature. They are both perennial. See Trefoil.

Saintfoin is a plant of the artificial graſs kind, which produces, Mr. Amos ſays, the beſt crops upon light rich land; but it will thrive upon the thinneſt lime-ſtone, gravelly, and chalky ſoils, with great luxuriance, even where theſe are ſo poor as to afford a very ſcanty crop of any of the other ſorts of graſſes. It thrives beſt when ſown alone, though it is frequently ſown with barley and oats, by cultivators that have not much experience of it. And it is adviſed, that upon whatever ſoil it is ſown, the land ſhould be brought into a very fine and clean tilth by culture. And, that about the latter end of March, or beginning of April, it ſhould be ploughed, and if it is roughiſh, be harrowed once in a place; then upon every acre, ſixteen pecks of ſaintfoin ſeed ſhould be ſown; then harrowing the land well, and ſowing eight pounds of common red-clover or trefoil, upon every acre afterwards, the land ſhould be buſh-harrowed and rolled. And, where weeds appear, they muſt be deſtroyed as they come up, by hand, or other means. It is recommended, that no ſtock be ſuffered to graze upon the ſeeds the firſt year; and, that if it be top-dreſſed with one quarter of rape or bone-duſt to an acre, about old Michaelmas, the plants are greatly invigorated and benefited by the application.

It is further ſtated, that, upon ſuch lands as the above, it furniſhes a crop of hay in ſummer of greater conſideration than any other of the artificial graſſes. The hay is excellent for all kinds of ſtock, and the after-math very good for cattle in autumn, and for ſheep in winter, till Candlemas. Hence, ſaintfoin is a moſt invaluable graſs on lime-ſtone, gravelly, and chalky ſoils; but it requires three years in coming to perfection; hence the propriety of ſowing common red-clover or trefoil along with it. And it ſhould be mown before it is in full bloſſom, otherwiſe there may be loſs in that way. See Saintfoin.

Lucern is aſſerted, by the above writer, to be the moſt productive, and that which comes into uſe ſooner than any other of the artificial graſſes. Horſes, beaſts, ſheep and pigs, are very fond of it, when it is mown and given them green, which is the moſt uſeful application of it. It is found to thrive beſt on rich, dry, loamy ſoils, which ſhould be made deep, fine, and clean of weeds by culture. And, he adviſes, that about the middle of April, ten pounds of ſeed ſhould be drilled on an acre, in rows of eighteen inches aſunder, and one inch deep, with a row of common red-clover between each; then buſh-harrowed and rolled. Nothing more is neceſſary to be done till weeds appear, when it ſhould be hand-hoed well, and the weeds in the rows pulled out by the hand. As ſoon as more weeds appear, it muſt be hand-hoed and hand-weeded a ſecond time, and even a third time, if neceſſary; when this is done, great care ſhould be taken not to tread upon the young lucern. And as ſoon at it begins to bloſſom it ſhould be mown, carried off, and given to the ſtock green. By this mode of application, it will, he ſays, keep more ſtock than any of the other graſſes.

But this plant alſo requires three years in coming to perfection; hence the propriety of ſowing common red-clover along with it. After that time, it may be mown three, four, or five times in a ſeaſon. But, between every mowing, it ſhould be well hand-weeded, and made quite clean of weeds. And every third year it ſhould have a covering of rotten dung, after the rate of eight or ten tons to the acre, applied over it about Martinmas. See Lucern.

Burnet is a graſs of the artificial kind, of which there are ſeveral varieties; but the only one worth cultivation in this country is the common ſort. This plant, though little cultivated, is highly valuable, either green or in hay for horſes and cattle, and is an excellent winter food for ſheep. It delights moſt in a dry, clean, light and deep ſoil; but it will grow very well on poor, gravelly, and chalky ſoils, which muſt be made clean and fine by culture. And it is adviſed by Mr. Amos, that, "about the middle or latter end of July the land ſhould be ploughed for the laſt time, and harrowed well: after theſe operations, four pecks of ſeed ſhould be ſown broad-caſt upon every acre, and then buſh-harrowed and rolled. And it is ſuggeſted, that as the proper ſeaſon for ſowing it is the latter end of July, it becomes an excellent ſuccedaneum to turnips, when they have been deſtroyed by the fly, which is often the caſe." And it is ſtated, that "the moſt profitable way of cultivating burnet is by ſowing it with other ſeeds, when the land is to be laid down in theſe proportions:

Names of Seeds.	Quantities.
Burnet-ſeed	1 peck
White clover	10 pounds
Trefoil	4 ditto
Vernal-graſs	¼ peck
Ray-graſs	1 ditto
Creſted dog's-tail	¼ ditto
Sheep's-feſcue	¼ ditto

The land ſhould be buſh-harrowed and rolled, and afterwards kept clean of luxuriant weeds. It is, however, remarked, that "much as this has been extolled, yet it is ſeldom ſown either alone, or with other graſs-ſeeds, ſince the introduction of red and white clover; though its greateſt excellence is for winter-paſture in the feeds of ſheep, &c." See Burnet.

Chicory is likewiſe a plant of this deſcription, which may be found highly beneficial on many poor ſandy or gravelly ſoils, where other ſorts of graſſes cannot eſtabliſh themſelves. It is aſſerted, in the Norfolk Report, that "Mr. Bevan ſowed an acre of poor land, worth not more than 2*s.* 6*d.* rent, with chicory in 1793, and that the next year it produced 7*l* 10*s.* in ſeed." And the writer ſays, that he has taken ſeveral opportunities of recommending this graſs in that diſtrict. On large tracts of poor land, he is confident it would increaſe the produce tenfold; and it well merits trial, he thinks, on every ſoil in it. The objection which has been founded on its not being eaſily extirpated, is, he contends, of no importance, for tares ſhould be ſown after it on ſome ſoils, and turnips on others, in which ſyſtem, its diſtinction is unqueſtioned. This hint ſhould not ſlip the notice of cultivators in other diſtricts.

Summer Tare.—This is a plant of the kind, which is much employed as ſummer herbage, either paſtured or mown green, as ſoiling for horſes, &c.; for hay, as a ſubſtitute for red clover (on land that has been tired of growing it); for manure to be buried in by the plough: and for ſeed: hence the ſeaſon for ſowing the ſeed of this tare will depend upon the uſe it is intended for. When for ſummer herbage, &c. it matters not how early the ſeed is ſown, provided no hard froſt enſue. The firſt ſowing may be as early in February as the ſeaſon and condition of the ſoil will allow, and to continue the ſowing at due intervals through the months of March and April, which will give a good opportunity for ſucceſſions of them, to the great convenience of ſummer-feeding, but when for depaſturing, it will be prudent to wait till the tares have gained a ſufficient increaſe of haulm, before the ſtock are turned in upon them. And when for ſoiling horſes, &c. they ſhould be mown before they flower; and in no inſtance ſhould the haulm be ſuffered to become rotten near the ſurface of the ground, which frequently happens on rich ſoils and moiſt ſeaſons. If for hay, as a ſubſtitute for red-clover, the ſeed ſhould be ſown as early in March as circumſtances will allow; but the time of mowing is more optional. Some mow them when the bloſſoms are fuller; others, juſt before they are quite ripe. But, in either caſe, the ſame caution is neceſſary, as in making ſaintfoin and clover into hay; and that is, to avoid breaking off the leaves, in which a great part of their virtue reſides. When they are intended for manure, the ſeed ſhould be ſown as early in February as the ſeaſon and condition of the ſoil will permit, and at the rate of four buſhels to the acre. For this uſe they ſhould be ploughed in before they get too long in their growth. But whatever is the intended uſe in cultivating this tare, the preparation of the land is the ſame; and this plant delights moſt in light ſandy ſoils: and, in every caſe the land ſhould be ploughed and harrowed once in a place, before the ſeed is ſown; then ſow the ſeed broadcaſt at the rate of three buſhels an acre for the firſt and ſecond uſes, harrow the land well afterwards, and then lay it dry.

"The great objects in cultivating this tare are, 1ſt, ſpring-food and ſummer-herbage for cattle and ſheep, eſpecially ewes and lambs. 2d. Hay, as a ſubſtitute for red-clover. 3d. Manure, to be buried in by the plough. And 4th. Seed. But whatever is the intended uſe of this tare, Auguſt and September is the prime ſeaſon for ſowing the ſeed of it. As ſoon, therefore, as the ground can be cleared of its crop, the land ſhould be ploughed and harrowed once in a place before the ſeed is ſown upon it." And it anſwers extremely well ſimply as a ſpring-food, when ſown with rye, in the proportion of ſix pecks of each to the acre. See Tare.

Where they can be cultivated, crops of this ſort ſhould never be neglected. See Artificial *Graſſes.*

Grass-*Ground*, in *Gardening*, the parts of ornamented grounds which are kept in the ſtate of lawn ſhort graſs or ſward. Thoſe ſpaces which are extended in the fronts of the houſes or habitations, and are termed lawns, are moſtly kept in ſhort graſs, which, by their conſtant verdure, ſummer and winter, and open rural appearance, exhibit a fine imitation of nature at all ſeaſons, eſpecially when the ſide boundaries terminate in rural plantations in various natural curves and bendings. This mode of laying out pleaſure grounds prevails much at preſent. But beſides theſe it is the practice to have rural ſhort graſs openings continued between the plantations throughout the different diſtricts of ground of this ſort, ſeparating and bounding the ſhrubbery clumps, borders, and other parts, in ſome places widely ſpreading, in others more contracted; but, in either caſe, extending to the boundaries of the ſeveral plantation compartments, in various bendings, ſweeps, and curves; by which the whole is rendered rurally ornamental, and at the ſame time more agreeable and eaſy to walk on than gravel between the plantations, when the weather is dry and hot during the ſummer ſeaſon. In the ancient ſtyle of gardening, it was much the cuſtom to have ſtraight ſhort graſs-walks, both for ornament and common walking upon: but for ornament, unleſs elegantly wide and ſpacious, they have a littleneſs in their general appearance, as may be ſeen where long narrow ſlips of ſhort graſs-ground are extended to ſome diſtance, in the way of walks; and for the latter purpoſe they are very improper in winter and all moiſt weather; and even in ſummer in the mornings and evenings, as being always damp and dewy. Walks of this kind ſhould therefore be but ſparingly introduced; and where any are made for variety, ornament, or ſummer's walking, they ſhould be as ſpacious as the ſituation admits, not leſs than from ten to fifteen feet wide, and even twenty feet wide or more, when the walk is conſiderably extended in length.

The method of forming ſhort graſs-ground work is either by ſowing the parts with graſs ſeeds, or by laying them with turf cut from a fine field, common, or down; the latter of which, where it can be obtained at a moderate expence, is greatly preferable, as it not only at once forms a complete ſward, but is generally more cloſe, even, and ſmooth, as well as leſs apt to run up to benty graſs, grow rank, or riſe in tufts, than by the ſowing method. The ſowing method is, however, much leſs expenſive.

Preparations.—In preparing the ground either for ſowing graſs ſeeds upon or laying with turf, the whole muſt be broken up equally to a moderate ſpade's depth, clearing out all the roots of perennial weeds and other coarſe materials. When this has been done, ſtakes or wooden pegs with notches, for making the level, according to the poſition of the ground, muſt be driven in; then proceed with line and ſpade to rough-level the ground according to the marks or levels on the pegs, afterwards treading, rolling, or ramming the whole down equally, that it may nowhere ſink in hollows afterwards. When this has been finiſhed, the levels ſhould be wrought up more accurately, and the whole finiſhed with a neat raking, clearing off all large ſtones, and making an even and ſmooth ſurface; in this ſtate it may either be ſown with graſs ſeed, or laid down with turf.

For the firſt method the proper ſeaſons for ſowing are either February, March, and April, or in Auguſt or September in moiſt weather. In moiſt wet ſoils the former is probably the beſt, but in thoſe of a dry gravelly nature, the latter. In this buſineſs it is of the utmoſt conſequence to procure good ſeeds; thoſe from hay-ſtacks or out of haylofts are often uſed, which may anſwer well, where the hay was the growth of ſome fine paſture free from weeds, and naturally afforded fine turf when grazed and mowed; but in other caſes there is often a mixture of various ſorts with weeds, by which the ſward is rendered irregular and foul, and never makes handſome ſhort graſs-grounds. If you are not furniſhed with ſeeds of your own, they muſt be obtained from the ſeedſman, and ſhould be of thoſe kinds which ſtrike deep root, ſpread out laterally in their tops, are permanent, and capable of reſiſting the effects of heat; there are many of this kind. (See *Laying* LAND *down to Graſs*.) The ſeed muſt be ſown broad-caſt, very thick and regular over the ſurface, and directly raked or harrowed in; and when the ſurface is dry it ſhould be rolled with a wooden roller, to bury the ſeeds more effectually, and make a ſmooth ſurface: when the graſs comes up, all weeds ſhould be removed; and the ſame ſeaſon, when the ſward is become thick and green, and advanced ſome inches in growth, it ſhould be mowed, rolling it well afterwards, and continue mowing it and rolling two or three times the firſt ſummer, eſpecially if it were ſown in ſpring, as, the oftener it is mowed and felled, the thicker and finer it will grow; and if it be intended to keep the graſs tolerably fine, mowing will be requiſite once a week or fortnight, according to the growth from April to October, and rolling once a week or fortnight in moderately dry weather, and occaſionally in the winter ſeaſon. In this way a good turf may be formed in a few years.

In the ſecond method, which ſhould always be employed where it can with convenience, the beſt turf is that of a fine paſtured common or down, where the ſward is fine and ſhort, with conſiderable cloſeneſs.

The beſt ſeaſon for laying the turf is from September till March or April, though it will grow at almoſt any time of the year, even, if there be occaſion, in the ſummer months.

The turf for this uſe is moſtly cut or flayed with an iron inſtrument called a turfing iron; all the turfs being cut of an equal width, length, and thickneſs; the proper ſize is a foot wide, a yard long, and about an inch in thickneſs. They ſhould be firſt marked by a line the proper width, length, and depth, and then cut with a racer or cutter, firſt longways a foot wide, then acroſs in yard lengths, proceeding afterwards to cut them up; having particular regard to cut them level, and all of an equal thickneſs, otherwiſe it will be impoſſible to lay them level. As they are cut they ſhould be rolled each up cloſe and tight, the graſs ſide inwards, and piled up by tens, eſpecially if they are cut by the hundred, which is moſtly the caſe. This is uſually done at from about a ſhilling to fifteen pence the hundred, according to the nature of the ſoil, as, whether ſoft and eaſy to cut, or hard and ſtony. A man will cut from three to five, ſix, or ſeven hundred a day, with a perſon to trace them out and roll them up as they are cut from the ſurface.

The method of laying them is very eaſy: they are placed regularly turf and turf, unrolling them as they are laid, joining them up quite cloſe edge to edge, and making good all deficiencies of broken parts as the work proceeds; and as ſoon as laid, they ſhould be well beaten with broad heavy wooden beaters, as flat pieces of elm or oak plank two inches thick, fifteen or eighteen inches long, and a foot broad, having long handles fixed ſlanting in the middles of the upper ſides. With theſe beat the graſs regularly all over, and then roll it well with a heavy iron or ſtone roller, repeating theſe operations in moiſt weather as there may be occaſion.

When very dry hot weather ſucceeds, ſo as to occaſion the turf to ſhrink and open at the joints, a good watering is of much advantage to it.

The management of ſhort graſs-ground, after it has been thus laid down, is that of mowing it in ſummer frequently, to keep it ſhort and fine, like a paſtured down; poling occaſionally with a long pole, to ſcatter the worm-caſts, which greatly deface all ſhort graſs, and rolling it frequently both to take up the ſcattered worm-caſts to make the ſurface clean, and to render it ſmooth, firm, and even in its appearance.

Mowing once a week, ten days, or a fortnight, or, according to its general growth, during the ſummer, is neceſſary, eſpecially for the principal home lawns, and other ſhort graſs-grounds, in the moſt conſpicuous parts; which parts ſhould always be kept very cloſe and fine, like the ſward of a fine paſtured down or common: it is performed with a ſhort graſs-ſcythe; and dewy mornings, or moiſt weather, muſt always be choſen for the work, as it will be impoſſible to mow ſhort graſs properly in dry weather. Previous to mowing, it is of advantage ſometimes to pole and roll the graſs the day before it is intended to mow. In performing the work of mowing, proper attention is neceſſary not to ſcore or leave the marks of the ſtrokes of the ſcythe, which has a very unſightly appearance; to prevent which, as much as poſſible, the point of the ſcythe ſhould be laid out rather wide, an inch or two beyond the meaſure of heel and point, eſpecially for very ſhort graſs, keeping the point rather out, and not drawing that part too faſt inwards, gathering the graſs neatly to the left in a range; and after having mowed thus to the end of the ſwarth, to mow it lightly back again, in order to trim off all ſcores, and other irregularities, unavoidably left the firſt time in executing the work.

After it has been all thus mown over, proceed to ſweep up the mowings of each ſwarth regularly, by ſtanding in the middle, ſweeping it along alternately to the right and left, to the end of the ſwarth, forming all the graſs in a range on each ſide; then ſweep up the ranges in large heaps, and carry the whole off directly in a wheel-barrow, large baſket, or other contrivance for the purpoſe.

The buſineſs of poling is performed by a long, taper, pliable, aſhen pole, fifteen or eighteen feet long, by paſſing it backwards and forwards, in rather dry weather, ſo as to break and ſcatter the worm-caſts about. The graſs ſhould be afterwards rolled with a wooden roller, when the ſurface is a little moiſt, but not too wet, by which the earth will all adhere to the roller, and render the ſurface perfectly clean, the work being repeated, as there may be occaſion, the year round; and in mowing-time, if the ſurface is foul, it is particularly neceſſary to pole and roll on the day previous to mowing, by which a clean ſmooth ſurface will be provided, ſo as to be able to mow cloſe, even, and more expeditiouſly. See POLING.

In the rolling of ſhort graſs-ground, it ſhould be performed occaſionally with a wooden roller, and a heavy iron or ſtone roller: the wooden roller is proper after poling, to clean up the worm-caſts and ſmooth the ſurface, being performed when the ſurface is not very wet, eſpecially if full of worm-caſts, as it would otherwiſe plaſter and daub the graſs, and render it unſightly; the heavy iron, or ſtone roller, ſhould be uſed occaſionally, when the ſurface is dry, to preſs down all inequalities, ſo cloſe as to preſerve a firm, even, ſmooth ſurface. And in fine-kept ſhort graſs-grounds, the rolling ſhould be performed occaſionally a day or two before mowing, to ſettle the ſurface firm and ſmooth, which greatly contributes to the eaſy and exact performance of the work: the buſineſs of rolling in ſmall, or but moderately large ſhort graſs-grounds, is moſtly performed by men; but in very extenſive grounds, it is ſometimes done by a horſe; having a large roller for the purpoſe, with ſhafts like a cart, and the horſe at the time wearing a ſort of leathern ſhoes, very broad at bottom, made ſo as to lace on occaſionally, like mens' half-boots, to prevent his feet cutting the ſurface in holes, and rendering it uneven, and of a bad appearance.

Where ſhort graſs-grounds are defaced by wild daiſies, dandelion, or other weeds, the firſt may be removed by having the blade of an old broad-ſword fixed in the end of a long pliable pole, which, as it cuts both ways, by ſweeping it backwards and forwards, it will head down the daiſies at a great pace; which may be repeated two or three times a-week, or as often as there may be occaſion for it.

The others ſhould be extirpated by means of an iron for the purpoſe, made in the form of a ſmall docking-iron.

In the autumnal finiſhing mowings, the graſs ſhould be generally cut down as cloſe and even as poſſible, that the ſward may remain in a neat even ſurface over the winter ſeaſon, and appear well in the early ſpring.

Theſe directions for the management of ſhort ornamental graſs-grounds, regard only ſuch as are required to be kept conſtantly ſhort, cloſe, and even in the ſurface, as is neceſſary in the principal lawns, plats, walks, and other diviſions, ſituated within the limits of the main pleaſure-ground. In the outward conſiderably extended diſtricts, continued into fields, parks, &c. it is not neceſſary to have them cut ſo frequently; two or three common mowings in a ſummer, with occaſional rollings afterwards, may be ſufficient.

Grass-*hearth*, in our *Cuſtoms, grazing*, or turning up the earth with a plough. Hence the cuſtomary ſervice for the inferior tenants of the manor of Amerſden in Oxfordſhire, to bring their ploughs to do one day's work for their lord, was called *graſs-hearth*, or *graſs-hurt*.

Grass *Huſbandry*, that ſort of huſbandry which has a relation to the management of graſs-land, or ſuch as are under the condition of ſward. This, in a great meaſure, conſiſts in the proper clearing, manuring, paſturing, or feeding down, ſhutting up, cutting or mowing, and the preſervation of the crops. This ſort of management is far from being perfectly underſtood in many parts of the kingdom, and conſequently the graſs-land is frequently in the moſt coarſe and wretched ſtate, being over-run with various kinds of coarſe and aquatic plants, as well as thoſe of the moſs, and other deſcriptions. See Husbandry, Grass, Meadow, and Pasture.

Grass-*land*, that ſort, or deſcription of land, which is moſtly preſerved in a ſtate of herbage or ſward. The ſorts of land that are the moſt adapted for this purpoſe are, according to ſome late writers,

1ſt. Such as are ſituated near large populous towns, where manure is cheap and plentiful, and where the produce of graſs-land is conſtantly on demand, and, of courſe, dear,

2dly. Such lands as are placed on the banks of rivers and brooks, that may be improved by irrigation to a much higher value than can poſſibly be done under any other method of cultivation.

3dly. Such lands as lie in vallies of mountainous countries, eſpecially chalky ſoils, where old meadow-land is ſcarce and valuable, and the greater part of the arable land is of that nature and quality, that it is impoſſible to convert it to good ſward-land. And

4thly. All ſuch cold ſtrong ground of the graſs kind, which, if ploughed up, would not be applicable to the purpoſes of the turnip-huſbandry, or thoſe of modern farming, and which, under the beſt practice of wheat-huſbandry, would not be ſo valuable as they are at preſent in the condition of ſward.

The forming of graſs-ground is effected with different degrees of difficulty in different inſtances; in ſome parts of the iſland it is accompliſhed, in general, with great care and facility, the ſoil having a natural tendency to the production of graſs herbage, when left in an unploughed ſtate, reverting to paſture without labour, expence, or even the ſowing of ſeed; while, in other caſes, all the art of man has been found ineffectual, to make good graſs-land. Even after 20 years fruitleſs expectation and expence, the land-holders have often been obliged to reſtore the ground again to a ſtate of tillage-huſbandry.

It is remarked, that conſequently the great difficulty in this buſineſs is to diſcriminate what ſort of land is ſuitable and proper for graſs, and that which is improper for the purpoſe. The beſt meadow-land does not always make the beſt tillage-land, nor does the beſt arable-land always make the beſt paſture, but frequently the reverſe. To make this diſcrimination, it is neceſſary to conſider well the proceſs of nature in propagating and perpetuating graſſes. The great object of nature is to perpetuate all her ſpecies; but upon the plants created for the ſupport of animals intended for the food and uſe of man, ſhe ſeems to have beſtowed more than ordinary care. Different kinds of animals propagate in different modes, ſome oviparouſly and ſome viviparouſly. Plants having no locomotive motion are endowed with a power of propagating in both modes. In trees and ſhrubs, and many kinds of plants, the aſſiſtance of man is required to obtain viviparous production, by grafting, budding, &c. But, in graſſes, nature does her own work, and that in both modes. We have only to attend to her examples, and we ſhall ſeldom err. In trees and ſhrubs, the bud is the viviparous production; in graſſes, the root performs the ſame office. Graſſes are as much the offspring of roots as of ſeeds. Every new root contains the germ of a future plant; and, as the ſeed-ſtalks of graſſes muſt neceſſarily be frequently cropped by animals, nature makes up the deficiency by an increaſe from the roots. Moſt of the beſt graſſes are, in their nature, biennial; but nature, by giving them the power of propagating by the root, has in effect made them perennial: a much more certain mode of propagation than by ſeed, as being increaſed inſtead of being injured by the biting and treading of animals, and by the produce being perfect in one year inſtead of waiting two, as in the production by ſeed. But this proceſs does not go on ſucceſsfully, unleſs the land is peculiarly apt for the production of graſſes. If it is too wet, the graſſes will be injured in the winter by rain and froſt, and will ſoon be ſuperſeded by ruſhes and other aquatic plants: if too dry, they will be killed by the ſummer's heat, and give place to moſſes, fern, heath, &c. No land will, it is conceived, make a good meadow, unleſs it is deep enough to admit the roots of graſſes to run down out of the reach of the ſummer's heat, and that it be retentive enough to hold water juſt ſo long as to produce fermentation, with ſuch an abſorbent under-ſtratum as will drain it before putrefaction takes place.

Some proportion of graſs-land ſhould always be attached to every farm, in order that a proper and ſuitable ſupply of winter and ſummer food may be provided for ſuch animals as may be requiſite in managing them, and alſo that adequate proportions of good manures may be raiſed; as, where this is not the caſe, it is impoſſible that farms can be well managed. And on all ſorts of graſs-lands, it is of much conſequence to keep them as clear and free as poſſible from the growth of all ſorts of coarſe plants, thoſe of the aquatic kind being removed by ſuitable drainage, and the application of different ſubſtances of the abſorbent deſcription to the ſurface of the land. They ſhould likewiſe be carefully eradicated from the hedge-rows of graſs-fields annually, and by that means be prevented from ſpreading themſelves over the ground by their ſeeds. By this practice, the hedge-plants would alſo be greatly benefited. Theſe ſorts of lands ſhould alſo be kept as clear as the nature of their application will admit, of all kinds of obſtacles that impede the production of perfect ſward, ſuch as the growth of moſs on their ſurfaces, and the continuance of cattle dung-hills, ant and mole hills, as well as thoſe of ſticks, ſtones, and other ſimilar ſubſtances. The proper methods of removing theſe are noticed under their particular heads, and in ſpeaking of meadow-lands, and paſtures.

According to the Agricultural Survey of the County of Hertford, in harrowing, with a view to deſtroy moſs, no benefit has been found to be produced, though the moſſy material has been well torn up. It is adviſed that manure ſhould be laid on at the ſame time: but that where aſhes are ſpread out over the ſurface without harrowing, the moſs plant is deſtroyed, and the graſs greatly improved. And in other caſes, much advantage has likewiſe been experienced from the application of fine ſand over the ſward, in an even but not too thick a manner. But the dung of animals ſhould never be ſuffered to remain any length of time in heaps upon the ſurface of graſs-lands, without being beat out ſmall, and diſperſed over the ſurface; as, wherever that is the caſe, the ſward in the places becomes tender, and the graſs comes up coarſe and in tufts, which are not eaten by cattle ſtock, and of courſe much injury ſuſtained.

In reſpect to the prevention of the riſing of ant-hills on graſs-lands, they may be in a great meaſure, if not wholly, guarded againſt, by having recourſe to frequent heavy rolling; as in the rolling down of ant-hills, inſtead of cutting them up, in an experiment made by the duke of Grafton, it was found to be attended with complete ſucceſs, on a large paſture which had been very much infeſted with ants, and which they had almoſt covered with hills. But in ſuch caſes the rollings ſhould be performed both in the autumn and ſpring ſeaſons, when the lands are in ſuch ſtates of moiſture as juſt to admit the impreſſion of the roller without receiving injury from the feet of the horſes; as, where ſuch operations are executed when the grounds are in a ſtate of conſiderable dryneſs, the benefits are comparatively ſmall. The beneficial effects that are produced in this way depend much upon the degree of conſolidation that is effected; as it is only by this means that the inſects can be prevented from carrying on their operations; a certain ſtate of lightneſs as well as fineneſs in the mould being eſſential to the execution of their labours in a perfect manner. But beſides theſe, attempts have been made in other ways to prevent the formation of theſe hills. For as it has been ſeen that "the economy of the ant requires the ſituation and ſoil to be dry, light, and friable, in order to carry on their works, it is probable that, in lands that will admit of the practice, it may be an eaſy and convenient method of deſtroying them, and preventing the bad conſequences which their labours produce on the ſurface ſward, to conduct water over them; and thus, at the ſame time, exterminate the colonies of ants, and irrigate the ground; by which two improvements may be effected at once,—the land being cleared from ant-hills, while its fertility is conſiderably increaſed." And the uſe of night-ſoil, in combination with various ſorts of earthy matters, has been adviſed with the intention of deſtroying ſuch inſects; but this is probably a practice that can only be depended upon in ſlight caſes. See ANT-*hill*.

Upon ſtiff yellow clays, a Hertfordſhire farmer has found the practice of draining, according to the Eſſex mode of carrying off the ſurface-water, uſeful, though this practice is totally unuſed by his neighbours in the ſame pariſh. Experience has convinced him, that dreſſing a cold tenacious clay not previouſly drained is an abſurd waſte of time, money, labour, and every thing moſt valuable. Having obtained a tolerably dry ſurface, his next object (with meadow-land) is to deepen the ſtaple of the ſoil, and this he does by every kind of compoſt carried on it for two or three years together, which he finds eſtabliſhes a better ſort of graſs than dreſſing once in three years on the ſurface.

It is ſuggeſted that the cuſtom of feeding the firſt year, inſtead of mowing, is a practice that muſt be preferable or not according to the nature of the ſoil, and the object of converting it into graſs-land. With reſpect to the former, he has found, that if he was to allow even the treading of ſheep the firſt year after the graſs-ſeed is ſown, he ſhould fill the ſurface with receptacles for water, and ſhould have very little, if any, graſs of a coarſe quality, notwithſtanding his drains; becauſe the ſheep or cattle would preſs the clay ſoil ſo cloſe, that the water could not penetrate into them; whereas, if he ſhuts up his field, ſuffering the graſs to ſtand till it ſheds the ſeeds, he finds the following ſeaſon that he is enabled, by giving only a ſlight dreſſing, to cut a good crop of hay from it. And in caſes of old worn out thin patches or moſſy graſs-lands, the practice of ſcarifying or cutting the ſurface ſward, in different directions, by implements for the purpoſe, has been lately adviſed as very beneficial in promoting their improvement, eſpecially where they are afterwards manured, and have ſuitable graſs-ſeeds ſown over the thin or patchy parts, as in this way the graſs-plants become more ſtrong and vigorous. In performing this buſineſs, Mr. Amos has adviſed the uſe of a machine for ſcarifying and dreſſing graſs-land, whether it is to be mown or depaſtured with animals. And he conceives that the beſt time of performing this operation, is from the middle of February to the middle of April. And that, in general, dreſſing the land one way is ſufficient; but, if the ſward be very moſſy or adheſive, it ſhould, he thinks, be dreſſed length and croſs ways, cleaned, and then rolled, the coulters of the implement being occaſionally cleaned from the rubbiſh. It is alſo ſuggeſted, that if the ſward be thin, it may be thickened very much by laying eight or ten tons of rotten dung upon it, and ſowing ſeven pounds of white clover, four pounds of wild or cow-clover, four pounds of trefoil, four pounds of rib-graſs, and one peck of beſt rye-graſs ſeeds, per acre, previous to its being dreſſed or buſh-harrowed, and then cleaned and rolled. It is ſuppoſed that by dreſſing land in this way, moſs is torn up, ant and mole-hills levelled and deſtroyed, the roots of the graſs cut and horſe-hoed, which cauſes them to throw out freſh lateral ſhoots or ſtems, the ſward thickened, and the ſurface made ſo clean as to put on the appearance of a perpetual ſpring when cloſe fed down. And that, by ſuch management, and grazing as much ſtock as will keep the graſs in a young ſucculent ſtate, and hobbing or mowing all the tufts and weeds three times in the courſe of the ſummer, the grazier will be enabled to receive every benefit from his land, and likewiſe prevent the ſtems of ſeveral graſſes from running into ſeed, and being injured in conſequence of it.

But another method of improving graſs-lands, practiſed by Mr. Salter of Norfolk, is ſaid to be original, and of great importance. It is ſtated in the Norfolk Survey lately publiſhed, that "upon his large farm of above 800 acres, he found 3 or 400 acres of old meadows entirely poiſoned by ſprings, which, from every ſort of impediment that neglect could cauſe, had formed bogs and moory bottoms, famous for rotting ſheep and miring cows; with blackthorns and other rubbiſh ſpread over large tracts. His firſt operations were, to grub and clear the land, and open all ditches to the depth of four or five feet, and to cut open drains in almoſt every direction for laying them dry; burning the earth, and ſpreading the aſhes on the ground: ſo far, the reporter ſays, all was no more than common good huſbandry; but he applied a thought entirely his own: as he found that the flinty gravel, marle, and other earths, but eſpecially the gravel, was very beneficial to the herbage, he thought of ſowing winter tares and white clover upon the places wherever any earth was ſpread, or any other operation had laid bare the ſurface, harrowing in thoſe ſeeds. The writer had the pleaſure of ſeeing ſeveral of theſe crops growing: the ſucceſs has been uncommonly great; for the land thus ſown not only has given large and very profitable crops of hay, but has alſo received a rapid improvement in the herbage; the cover and ſhade of the tares, ſo beneficial to all land, mellowed the ſurface, and ſeemed to draw up as well as protect ſuch of the old plants as received improvement from the manure, and exhibited a much ſuperior fleece of graſs to any ſpots where this ſingular management had not taken place. So that nothing can be clearer, on viewing this large tract of meadow, than the ſuperiority of the improvement reſulting from the growth of the tares: the effect of the manure is much accelerated and rendered greater."

The reporter further hints, that "the idea is certainly applicable to many of the graſs-lands of the kingdom, eſpecially ſuch as are improving by the addition of chalk, marle, clay, loam, ſand or gravel: 40 loads an acre of any of theſe bodies will much improve coarſe or wet, or moory graſs-lands; and then to add tares ſecures an immediate profit, and makes the manure work much ſooner and more powerfully. He ſows ſome ſo late as the middle of May." An idea here ſtrikes the writer, which he ſhall venture to add; that "if he was to ſcarify any moſſy, hide-bound, or poor paſtures, &c. it ſhould be with a drill-ſcarifier, drilling in winter tares by every tooth of the ſcarifier; and he has no doubt but the tares would take well, and effect a conſiderable improvement, even without manuring." It is ſtated in addition, that "Mr. Salter has practiſed the tare huſbandry on meadows for ten years, but his firſt beginning was ſeventeen years ago, at Ellingham: the cockchafer-grubs had deſtroyed a part of a meadow; he harrowed in tares and ſeeds, and the ſucceſs was great." It is alſo ſtated, that "tare-ſeed running ſhort, he this year ſowed peas and oats mixed on ſome ſpots, and they are found to do well; and this huſbandry he purſues, whether he intends mowing or paſturing. The writer conſiders this a diſcovery of vaſt advantage to graſs huſbandry in general.

And it is likewiſe obſerved, that "Mr. Bevan's arable ſand, at Riddleſworth, joining to his low boggy meadows, gave him the power of carting ſand down hill at an eaſy expence; and thus he improved ſome parts of thoſe meadows to great effect: from 100 to 150 loads an acre were ſpread at the expence of *4l.* or *5l.*

In 1802 this method anſwered very greatly: theſe meads were then not capable of irrigation, but one meadow has ſince been watered, and the water has taken much greater effect on account of the ſanding, than if that operation had not been performed. The ſand has all been laid on the moſt boggy meadows." This hint ſhould not eſcape the notice of the practical farmer in other diſtricts, as there are many where it may be had recourſe to, with the greateſt advantage and ſucceſs. There is likewiſe a ſimilar method of improving old rough and boggy meadow-land deſcribed, with a plate, by a writer, under the title of Agricola Norfolcienſis, in the firſt volume of the ſecond ſeries of the Agricultural Magazine, as practiſed by Mr. Rix, of the ſame county. "This meadow was ſituated at Clipſtone, near Fakenham, in the occupation of the above, and the property of T. W. Coke, eſq." of Holkham. It is noticed that "this meadow, from the neglect of former tenants, and want of judgment in cutting what few open drains or ditches were attempted, had become very rotten in many places, and at leaſt three parts of the four ſo over-run with ſedge and ruſhes, that its utmoſt annual value could ſcarcely be eſtimated at more than eight ſhillings per acre. The lands contiguous to it are of a light friable nature, inclining to ſand, by ſpots, and fall with a gentle declivity towards it from each ſide, the meadow being the baſon and receiver of the numerous ſprings which riſe in the upper fields, and which, in courſe of time, had rendered ſome parts of it utterly impaſſable for an horſe, and ſcarcely ſafe for a man at certain ſeaſons. It is obſerved that the firſt ſtep the preſent occupier took was, as ſoon after Michaelmas as he could, to cut the drains, as he has ſhewn in the plan; all of which are covered, except the main drain, and the two ditches. Theſe latter are cut both wide and deep, and are the chief operating checks to the ſprings above. And as ſoon as the weather permitted, he next ſet the teams to work (which were enabled to enter, even upon the moſt unſound parts, very ſhortly after the firſt proceſs was concluded), to level the hills, fill up the hollows, and to cart all the ſuperfluous mould he could collect within the boundary of the meadow, (ſuch as came out of the new-cut ditches and main drain principally), to the amount of 1000 loads, over the ſurface of the whole. About the laſt week of March he drill-rolled; and where the roller could not work, from little inequalities of ground, he dibbled the ſeeds mentioned in the annexed ſtatement, harrowing the ſmall ſeeds in afterwards; and, in July laſt, he cut and ſtacked the produce, which the writer has ſeen, and can witneſs to be excellent hay.

It is added that the preſent appearance of the meadow, after being fed down very cloſe by more than fifteen ſcore of ſheep, exhibits, notwithſtanding the very wet ſeaſon we experienced, one uniformly dry, firm, and ſmooth ſurface, completely covered with a ſhort turf, conſiſting of ray-graſs, Dutch-clover, and good natural graſſes. There are certainly ſome ruſhes yet, but far leſs numerous and ſtrong than heretofore, and which it may juſtly be expected a few ſweepings with the ſcythe, and hard ſtocking with ſheep, will in time wholly deſtroy. But though there may not be much

much novelty in the ſcheme of draining, the writer is of opinion, that very great merit is due to Mr. Salter, for the introduction of vetches, which he apprehends was never before tried on paſture-grounds, or indeed on any ground whatever unbroken by the plough. It certainly anſwers ſeveral admirable purpoſes, one is, that it gives a proſpect every year of a bulky crop of hay, which otherwiſe muſt have been very ſcanty. And being ſown with oats, the vetches afford that hovering kind of ſhade and protection to the young graſſes in which they moſt delight. The eddiſh is of courſe alſo worth more.

But he is not quite ſure, whether Mr. Salter's experiment gave riſe to the following practice, which he is informed daily gains ground. Where the clover plants fall partially, or by ſpots, on a new layer, ſpring vetches are often drill-rolled upon the ſurface, not ploughed. The few clover-plants are thus left to grow with the vetches, and both together, in due ſeaſon, form nearly as good a ſwath, as if the clover had not died away. Mr. Rix is ſo thoroughly convinced of the utility and advantage of the method he has purſued, that he is now preparing a ſecond meadow, lying at the foot of the one juſt improved, for a ſimilar proceſs of improvement.

In caſes where paſture-land can be ſpared for mowing, Mr. Salter ſeems to be of opinion, that vetches may be profitably employed, even a ſecond year, upon new improved meadows. He has had ſome experience of ſuch a repeated trial, and the writer believes he thinks favourable of it. He dibbles the ſeed upon the unbroken ſurface, after feeding it down as cloſe as he can with ſheep or other ſtock.

It is ſtated that the above meadow of Mr. Rix's cannot be over-rated, if it be ſaid that it is, at this moment, more worth thirty ſhillings per acre to a tenant, than, in its former ſtate, it was eight ſhillings the acre.

It is alſo neceſſary that care be taken to keep graſs-lands in a proper ſtate of production, by the judicious uſe of top-dreſſing, and by obſerving ſuitable methods of mowing and feeding them down by ſtock, and it becomes of courſe requiſite in the view of keeping ſuch lands in the moſt proper condition for the production of plentiful crops, as well as that of altering and improving the nature of the herbage, to have recourſe to the occaſional application of manure; as by this means the ſtaple and depth of the vegetable mould are not only much increaſed, but the land brought into ſuch a ſtate of fertility, as that it may afterwards be kept up with much leſs expence and trouble than before.

A late writer has ſtated, that "it is a circumſtance well known to graſs-farmers in the beſt cultivated diſtricts, that when lands of this ſort are ſuffered to get much out of condition, it is a much more difficult buſineſs to reſtore them to the proper ſtate of productiveneſs, than to preſerve them in it. From the conſtant decompoſition and decay of various vegetable materials on the ſurface of graſs-lands, new portions of vegetable mould are conſtantly added, that improve the quality of the lands, and at the ſame time afford a more ſuitable and fertile bed for the eſtabliſhment of the different kinds of graſs-plants. It is chiefly, perhaps, on theſe accounts that old graſs-lands are ſuperior to new ones, and it explains the reaſon of the greater utility of earthy compoſts with dung in the latter than the former caſes. However, with reſpect to the moſt proper periods of making ſuch applications, there is much difference of opinion; but it ſhould, probably, be regulated by circumſtances; ſuch as the ſtate of the land in regard to dryneſs, its ſituation, the heat of the ſeaſon, and its nature and condition in reſpect to ſoil and fertility. Where the land is ſuch as not to admit the dung-cart in the early ſpring-months, without the danger of injuring the ſurface by poaching or breaking the texture of the ſward, the moſt proper period would ſeem to be in the beginning of the autumn, before the heavy rains fall, as at this period the dreſſing may be laid on with the greateſt convenience and ſafety; and from the after-graſs being chiefly conſumed with the leaſt loſs in that particular. It is, however, recommended to be performed by ſome immediately after the land has been mown and cleared from the hay, in which method there may be an advantage in ſome caſes, as the growth of the after-graſs may thereby be rendered more abundant." But, in other reſpects, it has been obſerved by the author of Practical Agriculture, that, "it muſt often be not only inconvenient, but uneconomical, as, from its happening at a ſeaſon when much other buſineſs is to be performed, it can ſeldom be attended to in ſuch a manner as is neceſſary; and when the ſeaſon at this period is hot, and there is much ſun, as in general is the caſe, there muſt be conſiderable loſs ſuſtained in the extrication and diſſipation of the finer and more enriching particles, ſuch as become more immediately the food of plants, from their being in a condition nearly ſuitable for being abſorbed and taken up by the roots of the graſſes. The extent of the loſs incurred in this way is much more conſiderable than is commonly ſuppoſed, as muſt appear evident from the great exhalation and conſtant evaporation that is often kept up for many days, or even weeks, as the very offenſive ſmell that iſſues fully proves. In this diſtrict, where we have occaſionally witneſſed the practice, with ſome of the leſs intelligent farmers, the moiſture of the manure has been ſo much forced off and diſſipated, eſpecially when there is much wind, as to leave the materials in nearly a perfectly dry ſtate. The ſudden drying up of large ponds, at ſuch ſeaſons, ſhews in a more ſtriking manner the extent of the injury that the farmer ſuſtains in chooſing this ſeaſon for the application of his manure" upon his graſs-lands. And, it ſtill further ſtates, that "there is another way in which a vaſt loſs of manure may take place when applied at either of the periods that have been juſt noticed, eſpecially where the lands lie in ſloping directions, as is frequently the caſe, which is by the heavy rains in the autumnal ſeaſon carrying down the more fine and rich parts of the manure, in a ſtate of ſolution, into the ditches and runlets on the ſides or other parts of the fields. Of the great waſte of manure occaſioned in this way any one may convince himſelf, by attending to the ſtate of the water as it drains off from the higher grounds into theſe places, after the land has been previouſly dreſſed, as it will be found highly coloured, and loaded with the enriching carbonaceous particles of the manure." And "after froſts, when ſudden thaws occur, the ſame thing happens" in a ſtill more extenſive degree than in the other caſes.

In caſes where the natural dryneſs and open texture of the ſoil admit of the manure being applied in the early ſpring months, there will be leſs danger of waſte in the above manner, and at the ſame time greater advantage obtained in the growth of the produce; as, from the moderate heat and quickneſs of the vegetation at this period, the graſs will ſoon over-ſhade and conceal the dung, where laid on in a ſuitable ſtate of reduction or fineneſs, without ſuffering much exhalation to take place; and the enriching material be conveyed to the roots of the graſs-plants at the time in which it may be the moſt uſeful in promoting their growth. Where the principal object of the farmer is a large produce, and the nature of the ſoil will admit of the manure's being applied without injury, this is unqueſtionably the moſt ſuitable as well as moſt beneficial time of putting the dung upon graſs-lands. The earlier, however, it can be performed the better. See MANURE.

But it has been ſtated by ſome, that manure produces the ſtrongeſt effects upon the land when applied early in the autumn, or in meadows as ſoon as poſſible after they have had the hay taken off from them. And others ſuppoſe this laſt as the moſt proper ſeaſon for having the buſineſs performed in of any.

In regard to the kinds of manure that are moſt proper, there is ſcarcely any ſort that will not be beneficial when laid upon graſs-lands; in general, however, the more rich animal kinds will be the moſt ſuitable for the older ſorts of ſward-land; and dung, in combination with freſh earthy materials, the more proper on the new lays or graſs-lands, as by this means a fine earthy bed will be prepared for the roots of the graſs-plants to ſhoot and ſpread themſelves into, and a better ſward formed in conſequence of ſuch applications. See *Laying* LAND *down to Graſs*.

It is the practice of the beſt farmers in the hay-diſtrict of Middleſex to uſe the richeſt dung they can procure, without mixing it with any ſort of earthy material, as they find it anſwer beſt in the quantity of produce, which is the principal object. The lands on which this ſyſtem is purſued, are moſtly ſuch as have been long under ſward, and where the ſoils are chiefly of the more tenacious, loamy, or clayey kinds. It cannot, however, be doubted, but that earthy compoſts in the proportion of a third or fourth of ſuch materials may, in many caſes, according to the nature and circumſtances of the land, be had recourſe to with great and beneficial effects, both in rendering the land more productive, and in bringing the herbage into a finer ſtate, as well as in bettering the ſurface for the purpoſe of mowing. See MANURE.

It may be obſerved, that whatever the nature of the material may be that is employed in combination with dung, or the ſort of manure that is uſed, it ſhould invariably be brought into a rather fine ſtate. It is the practice, in the diſtricts mentioned above, to turn over the dung that is brought from London in a ſtate of tolerable rottenneſs once, chopping it well down in the operation, ſo as to be in a middling ſtate of fineneſs when put upon the land. It is neceſſary, however, that it ſhould be in a more rotten and reduced ſtate when applied in the ſpring, than when the autumn is the time of putting it upon the land.

In reſpect to the proportion of manure made uſe of at once, it ſhould be, in ſome meaſure, ſuited to the ſtate of the land, but, in general, ſuch as to afford a good even covering to the ſurface of the ground. Where the manure is of a very good and enriching quality, the quantity may be from four or five to ſix or ſeven loads on the acre, of ſuch as are drawn by three or four horſes. But where the manure is of an inferior quality, a much larger proportion may be requiſite and proper.

The frequency of dreſſing graſs-lands, in ſo far as it reſpects the ſoil, ſhould conſtantly be performed at ſuch diſtances of time, as that the fertility of the lands may not be ſuffered to decline, but be preſerved in an equal or increaſed ſtate of heart; in which the manner and frequency of cutting, or otherwiſe conſuming the produce, muſt be conſidered; as, where crops are more frequently taken off, the land muſt be prevented from being injured, by the great loſs of fertility that muſt ariſe in this way, by the dreſſings being applied at ſhorter intervals, or in larger quantities at a time; but the firſt is by much the beſt method, as injury may often be done by too great a dreſſing being given at once. But, in general, where ſuch lands are in a tolerable ſtate of cultivation, every third year may be ſufficient; while on ſuch as are of inferior value, it may be a better practice to do it every ſecond year, as by this frequent application of manure, the lands may attain a gradual improvement; whereas, in the contrary caſe, they would be on the decline, and in time become poor and worn out to the great injury of the farmer. It is a too common practice, in diſtricts where graſs-huſbandry is imperfectly underſtood, to almoſt wholly neglect the manuring of ſward-lands, in order to employ it on thoſe which are under the plough: but this is obviouſly bad management; as it is only by the raiſing of full crops of graſs for being converted into hay, and of proper kinds of green food, that a full ſtock of cattle can be kept, and the largeſt poſſible proportions of manure provided for the land. It may be noted there are a few articles made uſe of as top-dreſſings to graſs-lands, which cannot, it is ſaid, be frequently repeated with either ſafety or advantage, ſuch as chalk, marle, chopped woollen rags, and ſome others. It is ſtated, that "the firſt of theſe kinds, eſpecially when of a ſoft, unctuous nature, ſo as to readily fall down in the ſtate of ſolution to the roots of the graſs-plants, is found to produce the moſt beneficial effects, in rendering the lands more fertile and productive, and improving the quality of the herbage. It cannot, however, be often repeated in its ſimple ſtate with advantage, as it is ſome time in producing its full effects; but in that of compoſt, it may be applied with ſucceſs at ſhorter intervals. Marle is likewiſe a ſubſtance, eſpecially when it is of the rich, ſoapy kind; that may be made uſe of with much advantage as a top-dreſſing on graſs-lands; but as its operation is ſlow, it cannot be repeated at ſhort intervals, except when employed in the ſtate of a compoſt with dung-woollen rags, which, rendered ſmall by being chopped into pieces, may be laid on land in the ſtate of ſward; but as they require a conſiderable length of time to ſink down and become mixed with the ſoil, ſo as to be well covered by the graſs, they cannot be repeated at ſhort intervals. After they have been fully incorporated with the land, their beneficial effects are conſiderable," as have been fully ſhewn in the trials of different graſs-farmers: and there are various other matters that are occaſionally applied as top-dreſſings on graſs-lands; ſuch as lime in combination with rich vegetable earth or peat, the aſhes derived from the combuſtion of peaty ſubſtances, coal-aſhes, malt, duſt, and ſoot. Moſt of theſe have been made uſe of with good effects when thinly ſpread out over the ſurface ſwards of lands in the ſtate of graſs. The three laſt have been found to produce the beſt effects in being diſperſed over the new lays of the artificial graſs kinds. All applications of this ſort ſhould be applied in February, being ſpread over the ſurface as evenly as poſſible. "If it can be done before a ſhower of rain, it will be the better, as it is of advantage to have them carried down to the roots of the graſſes as ſoon as poſſible after they are laid upon the land." But ſome adviſe, in the "management of purchaſed manures, that experiments ſhould be formed for a year or two, before the practice is extended, to ſee which, at a given price, will ſuit the land beſt. Without this precaution, a farmer may probably expend large ſums of money to little purpoſe. Nor ſhould he truſt to the mere appearance of the effect ſoon after the manuring; for ſome of them, particularly ſoot and malt-duſt, will ſhew themſelves after the firſt heavy ſhowers, in a finer green than the reſt of the field; but the proof of the effect does not ariſe from fine greens, but from weight of hay: for it has been found from experience, that the latter is not always an attendant on the former. Contiguous half-acres, or roods, ſhould be marked out, the prices of the manures calculated, and on each piece a ſeparate one ſpread, all to the amount of 20ſ. an acre, for inſtance. At hay-time, the crops ſhould be weighed. It will then be known which manure, at the given prices, ſuits the ſoil beſt. This knowledge will prove true experience, and a very different guide from general ideas."

And here is ſtill another circumſtance neceſſary to be attended to in putting manure upon lands of this kind, which is not to ſuffer too much to be placed out in any of the heaps, but to have them ſet out as much as poſſible in moderate ſized portions, and "at regular diſtances from heap to heap; as, where the contrary is the caſe, it not only takes up more time, and cauſes much more trouble to the labourer in ſpreading them, but does not admit of the work being performed in ſo regular or ſo exact a manner. Beſides, when the heaps are ſet out too large, much injury is done to the graſs-plants on the ſurface where they ſtood, if not ſoon ſpread out, which ſhould always be the caſe, in the quickeſt manner."

It is alſo of much conſequence, in the execution of this buſineſs, to have convenient carts for the purpoſe, which, in general, are thoſe of the ſingle-horſe kind.

Some care is likewiſe neceſſary in the ſcaling or "ſpreading-out all ſorts of top-dreſſings on graſs-lands, to ſee that the work be performed in an exact and even manner, and that all the clods and lumps be well broken down and perfectly reduced by beating with the fork or ſhovel. If poſſible, a dry ſeaſon ſhould be choſen for this ſort of buſineſs, as, under ſuch circumſtances, it can be executed in the moſt regular and exact manner; as when the weather is wet, it is an operation that can never be well performed, as the materials clog round the feet and implements of the workman, and can never be effectually ſeparated or divided ſo as to be ſpread out with the neceſſary degree of evenneſs." It has been already noticed, that "after the heaps have been ſet out, they ſhould not be ſuffered to remain ſo long, as is often the caſe, before they are ſpread out, as the plants underneath them become blanched and tender, and great injury is done to the ſward in ſuch caſes, all of which may be eaſily avoided by ſpreading as ſoon as poſſible after the manure is taken out. Inconveniences of this kind may likewiſe be avoided by ſpreading the manure from the carts, as is the practice in the midland and ſome other diſtricts: but in this method it is ſuſpected the work can neither be executed in ſo exact a manner, or with ſo much economy of time or labour. In this way hill-ſteads will not be formed, and, of courſe, the diſadvantage of their getting too large a proportion of the manure prevented," as Mr. Marſhall has well obſerved in his Economy of the Midland Counties of the Kingdom.

The uſual practice, as ſoon as "the whole has been ſpread out, and remained in that ſtate for a fortnight or three weeks, or longer, according to circumſtances, and is become in ſome degree dry and powdery, to apply a buſh-harrow over the ſurface once or twice in a place, in order to reduce the manure into a finer ſtate, and bring it more fully to the roots of the graſſes. But this ſort of work, as that of ſpreading, ſhould never be attempted when the ſeaſon is wet, and the manure in a claggy, adheſive ſtate. As ſoon as this work has been executed, all the rubbiſh of every kind ſhould be carefully picked off, in order that the ground may receive the action of the roller," which ſhould be paſſed over it as frequently as may be thought neceſſary, when the land is in a ſuitable condition for receiving it. (See Rolling.) This is the principal buſineſs which is requiſite in the management of graſs-lands in general.

In Hertfordſhire, "a mode of managing ſound meadows and paſtures has lately been tried, and attended with great increaſe of produce. The graſs is mown as ſoon as it is in bloſſom, and conſequently previous to the formation of ſeed. The after-graſs is not grazed until it begins to contract a yellow appearance, in the latter end of October or the beginning of November. In this caſe the ground remains covered during the winter with a portion of dead herbage, through which the young graſs ſprings with the greateſt vigour. Mr. Knight contends, that the ſap in all plants aſcends through the alburnous veſſels of the root, and is diſperſed over the leaf, whence it is returned to form new roots and buds, and to prepare them for vegetation. According to this theory, if the leaves be eaten off on mowing ground, as ſoon as they are reproduced, the roots are deprived of their nutriment, and the plants in conſequence vegetate weakly in the ſucceeding ſpring. Whether this hypotheſis be well or ill founded, it is certain that the ground which is left with this portion of the leaves of graſs in the one ſeaſon, is much more productive, and more early in the next; and cloſe grazing will ever be found to decreaſe the quantity, although it ſhould improve the quality, of the following crops." It is evident that there is ſome truth in this, from its having been found that the crops are more early and abundant in different caſes, where the after-graſs is not fed down much in the autumnal ſeaſon with live ſtock. See Mowing and Grazing.

Comparative Quantity of Food from Graſs and Tillage Land.

With reſpect to the difference in the proportion of human food raiſed from graſs and tillage land, the firſt circumſtance neceſſary to be attended to, according to a late writer, is that commonly denominated *Price.* But theſe inquiries ſuggeſt a further idea concerning the part of the produce, of either graſs or arable land, to which that circumſtance is attached. It is evident, on the ſlighteſt view of the ſubject, that the portion of the produce conſumed in the farmer's family can have little to do with the price of the market: it never finds its way thither: it never comes to be meaſured with the demand of the conſumer, who does not produce. For this reaſon, in all inquiries that have for their object what is called plenty or ſcarcity, we never hear of any thing but price; and price is never formed but by the ſupply of towns from the produce of the country. The larger part of a modern ſociety conſiſts of the inhabitants of thoſe towns, who are ſupported either by manufactures, or on incomes not derived immediately from the cultivation of the earth. So much for juſt opening our way in a field rather intereſting: but may we not, with equal propriety, extend the circumſtance juſt alluded to, to the labouring families ſupported by the farmer? His little neighbours in the village who do the work of his huſbandry, arreſt, if we may ſo expreſs it, the amount of their ſubſiſtence from the crop before it arrives at the market. They muſt be fed; and though in many caſes, by buying their flour of a miller, they ſeem to claſs with the inhabitants of a town, yet, perhaps, in more numerous caſes they are, in fact, fed immediately from the farmer's ſtores; and in effect always ſo: for, if the farmer cannot produce his crops but by their direct aſſiſtance, and muſt multiply them exactly in proportion to the operoſeneſs of his culture, they cannot be conſidered in any other light, than mouths attached to the culture of the land, and demanding a deduction from the produce of wheat, before the ſurplus or market be reckoned, in as direct a deduction as that from his crop of oats for the food of his horſes, or other animals. It is added that there are in the Suffolk Report ſome eſtimates of what the writer calls produce free in the market, and he makes the graſs-lands yield a greater free produce (horſes, labour, &c. &c. deducted) than arable; and he knows not but it may be the ſame in other counties. Other writers ſeem alſo to have had the notion that graſs-land is more beneficial than arable. Bertrand, a Swiſs writer, ſays, that graſs-countries yield more food than arable, and therefore manufactures ſhould be fixed in them. Hartlib ſeems to be of the ſame opinion, and quotes thoſe of Europe as the moſt populous. Fortrey, who wrote in 1663, alſo ſays, that our chief care ſhould be to increaſe our ſtock of cattle. There is ſome degree of truth in theſe ſentiments; and they might be conſidered in relation to the proportionate nouriſhment, in a pound of animal food compared with that of a pound of vegetable, which ſome authors have made vaſtly greater in meat than in bread. Theſe are topics, it is ſtated, which ought to be thoroughly examined, that the public mind may be free from every erroneous bias upon ſuch points. But further in the dairy countries, where butter is the chief produce, four firkins, or 224 lbs. may be reckoned the average produce per cow; the calf ſold at about a week old, may contain about 30 lbs. of fleſh; and as the pigs ſupported by a dairy, uſed to be reckoned at the rate of 20s. per cow, when pork was 6*d.* per pound, it implies, that 40 lbs. of pork is the proportion to each cow: but the cow conſuming the produce of three acres, the acreable account would of courſe ſtand as below:

Acreable Account.	*lbs.*
In Butter - - - - -	74
Veal - - - - -	10
Pork - - - - -	13
Total	97

However, in the cheeſe counties, the products vary a good deal: in Cheſhire 4 cwt. per cow; in Shropſhire $2\frac{1}{2}$ cwt.; in Glouceſterſhire about $2\frac{3}{4}$ cwt.; in Wiltſhire 4 cwt.; in Somerſetſhire $3\frac{1}{2}$ cwt.; in Warwickſhire 3 cwt.: the average of all theſe is $3\frac{1}{5}$ cwt. and at three acres per cow, 1 cwt. and a ſmall fraction per acre; and as theſe counties are richer than thoſe applied to the produce of butter, veal may be called 15lbs. and pork 20lbs.; in all 147lbs. per acre, or thereabouts. But as to meat, authorities are not very ample: in the midland counties there is a very general notion, that an acre of graſs, at 40*s.* rent, will give 200lbs. of mutton. By an experiment made on land of an inferior quality, which is mentioned in the Annals of Agriculture, land of 16*s.* rent, gave 80lbs.; and he has heard, on good authority, that in Cambridgeſhire ſome obſervations, carefully made, confirmed this proportion of produce in land fed both with bullocks and ſheep; and the produce of beef, &c. in the Lincolnſhire marſhes, goes even further than this ratio or proportion to the acre.

With reſpect to the butter dairies, they are on land of about 16*s.* an acre rent; and if the produce be 97lbs. the proportion will be 6lbs. to every ſhilling rent. The cheeſe dairies, at 25*s.* rent, yielding 147lbs. are alſo at about 6lbs. per ſhilling rent. The meat is 5lbs. per ſhilling. It is eaſy then to decide, that dairy counties are more advantageous than grazing ones in weight of produce; but their ſuperiority is far greater in another point of view; their produce comes much more into the conſumption of the poor; for, where one poor perſon eats meat, there are probably forty that conſume butter and cheeſe. How to compare theſe products with thoſe of arable land is very difficult; and yet the inquiry is too intereſting entirely to be omitted: a long train of inveſtigation might enable one to diſentangle difficulties, but it would require much time to go deeply into ſuch a variety of ſubjects. The produce of a good loamy ſoil, under the courſe, 1. Turnips, 2. Barley, 3. Clover, 4. Wheat, may, it is ſuppoſed, be calculated in this manner.

" No. I. *Arable dry Land at 16s. an Acre Rent, five Acres each Crop; twenty Acres in all, in a Courſe of four Years' Huſbandry.*

	Time.		
	Perſons.	Years.	Weeks.
1. Turnips; eight ſheep an acre, at the increaſe of 5*s.* each ſheep, or 40*s.*; in mutton 80lbs.; and for 5 acres 400lbs. will be ſufficient (at $\frac{1}{2}$lb. per perſon per diem) for two perſons, one year and five weeks - - - -	2	1	5
2. Barley and oats; ſuppoſe an allowance of $1\frac{1}{2}$ acre of oats (at five quarters per acre) for one horſe as the proportionate team to twenty acres, and including ſeeds for $1\frac{1}{2}$ acre: in all ſixty buſhels; remain $3\frac{1}{2}$ acres for barley, at four quarters an acre; fourteen quarters or 112 buſhels; deduct fourteen for ſeed, remain ninety-eight buſhels for malt, &c.; but, if applied in bread, ſufficient at nine buſhels per head per annum, for eleven perſons a year, minus one buſhel.			
3. Clover; deduct two acres for the ſummer and winter food of the horſes, remain three acres for ſheep, at eight per acre, improved 8*s.* each, or 3*l.* 4*s.*; or (at 6*d.* per pound) 128lbs. of mutton, and for three acres 384lbs. ſuffi-			

		Time.	
	Perſons.	Years.	Weeks.
cient at $\frac{1}{2}$ a lb. a day for two perſons a year: and leaving 20lbs. over; -	2	1	20
4. Wheat; twenty-two buſhels per acre, which, after deducting feed, leave twenty, or $2\frac{1}{2}$ quarters, and for five acres $12\frac{1}{2}$ quarters, ſufficient for twelve perſons a year and two weeks	12	1	2
Whole produce in human food -	16	1	17
The ſame land, if in graſs, would give 80lbs. of mutton per acre, 400lbs. per ann. and for four years 1600lbs. ſufficient at $\frac{1}{2}$lb. a day to ſupport eight perſons one year and thirty-ſix days" - - - - - - -	8	1	36

Hence, "to make the deduction, before alluded to, of the farmer's family, and his labourers: ſuppoſe he farms an hundred acres, which is, probably, above the average ſize of farms of the kingdom, here are five perſons to that extent, or one to twenty acres. If we reckon all ſorts of labour at 21*s.* an acre, we ſhall, he ſuppoſes, not be far from the fact: the pay of a labourer may be reckoned on an average at 25*l.* which we ſhall call the food of five perſons; ſetting the earnings of the wife and children againſt rent, clothes, and other articles; this makes food 5*l.* a head: for every 5*l.* therefore that the farmer pays in labour, we may ſafely, he ſuppoſes, reckon that one perſon is fed from the produce of his farm before it reaches the market: the labour in the twenty acres in the above inſerted eſtimate being 21*l.* he calls four perſons', and the farmer's family one, making five, to be deducted from the acreable amount of the farm."

	Perſons.	Years.	Days.
Brought forward - - - -	16	1	17
Deduct - - - - -	5	0	0
Remains for market - - -	11	1	17
And the 20*s*, exceſs in the 21*l.* ſtrikes off - - - -	0	0	17
	11	1	0

Yet, "in regard to graſs land, as it is managed with ſo much more eaſe, and farms are generally ſo much larger, it will be fair to deduct only one perſon for farmer and labour."

	Perſons.	Years.	Days.
Brought forward - - -	8	1	36

Remain for market - - -	7	1	36

"It then appears, that under the circumſtances of ſuch land thus applied, arable land, on compariſon with graſs, ſends to market in the proportion of 11 to $7\frac{1}{10}$. But if the barley, inſtead of being drunk, be eaten in bread, it adds to the arable account eleven perſons, and the account would then ſtand nearly twenty-two to $7\frac{1}{10}$, or about three to one.

"But, as the largeſt part of the kingdom is employed in ſyſtems of huſbandry very inferior to this excellent one, let us calculate how the compariſon will ſtand with open fields, and thoſe incloſures which are managed by means of fallows in the ordinary rotation of cropping that is purſued upon them.

"No. II. *Open-field arable—Soil clay or wet—Rent* 10*s. an Acre, five Acres each Crop*; *thirty in all, in a Courſe of Six Years' Huſbandry.*

		Time.	
	Perſons.	Years.	Weeks.
1. Fallow:			
2. Wheat; produce twenty-two buſhels; ſeed two; for conſumption twenty, or $2\frac{1}{2}$ quarters; $12\frac{1}{2}$ quarters for five acres, being food for twelve perſons during one year and two weeks -	12	1	2
3. Oats: produce four quarters an acre; ſeed half a quarter; remain $3\frac{1}{2}$ quarters per acre, or $17\frac{1}{2}$ quarters, or 140 buſhels: ſufficient, at twenty-five buſhels a head, to feed five perſons a year and five weeks, if uſed in bread.			
4. Fallow:			
5. Barley; ſuppoſed to be conſumed in beer, &c.: but, if eaten by man, at four quarters an acre, deducting half a quarter for ſeed, remain $3\frac{1}{2}$ quarters or twenty-eight buſhels; and at nine buſhels a head, ſufficient for three perſons one year, and one buſhel over, and five acres, enough for fifteen perſons one year and two weeks.			
6. Beans; for horſes equal to the food of $1\frac{1}{2}$ horſe (at one horſe to twenty acres) for the year.			
	12	1	2

But the ſame land laid down to graſs, and let at 20*s.* will, he ſays, feed (on the ſuppoſition of an increaſe 5lbs. per ſhilling rent) oxen and ſheep to the addition in weight of 100lbs. of beef and mutton, or 500lbs. for five acres, and 3000lbs. in ſix years; which, at half a pound a perſon per diem, or 182lbs. per head per annum, will feed $16\frac{1}{2}$ perſons one year. The courſe here detailed does not feed the horſes in ſummer; but as it affords, perhaps, more horſe-food in the beans than to that amount, no other deduction ſhould be made. It appears, that thirty acres of ſuch land, when the oats and barley are eaten by horſes, or drunk by men, ſupport twelve perſons a year and two weeks; now from this we are to deduct, as in the former caſe, the population of the farmer and his labourers; the former in the ſame ratio as before; but 15*s.* will be enough to deduct per acre in labour, inſtead of 21*s.* in the other courſe. This will, on thirty acres, be 22*l.* 10*s.* or $4\frac{1}{2}$ perſons a year: add one and a half for the farmer, it is ſix in all.

	Perſons.	Years.	Weeks.
Brought forward - - - -	12	1	2
Deduct labour and farmer - -	6	1	0
Remain for market - - -	6	1	2
The graſs - - - - -	$16\frac{1}{2}$	0	0
Deduct $1\frac{1}{2}$ for farmer and labour, that is, one per 20 acres - -	$1\frac{1}{2}$	0	0
Remain for market - - -	15	0	0

But if the barley and oats be brought into the account as human food, the account will then ſtand in this way.

	Perſons.	Years.	Weeks.
Wheat - - - - - - -	12	1	2
Oats - - - - - - -	5	1	5
Barley - - - - - - -	15	1	2
ſay	32 for	1	2
Deduct for farmer and labour - -	6	1	0
Remain - - - - - - -	26	1	2

It is conſequently ſtated, that in one caſe, the graſs has the advantage as fifteen to ſix: in the other, the arable as twenty-ſix to fifteen.

"No. III. *Poor Sand or Heath—Rent 5s.; five Acres each Crop; thirty Acres in all.*

	Perſons.	Years.	Weeks.	Days.
1. Turnips: four ſheep an acre, to the increaſe of 6*s*. each, or 24*s*.; in mutton 48lbs.; and for five acres 240lbs.; ſufficient, at ½lb. per diem, for one perſon one year ſixteen weeks and four days - -	1	1	16	4
2 Barley and oats; one horſe to thirty acres, which demands 2½ acres of oats, at three quarters (ſeed deducted); the remainder therefore 2½ acres for barley, at 2½ quarters per acre, being ſixteen buſhels (ſeed deducted), and for 2½ acres forty buſhels remain for malt; but enough in bread, at nine buſhels a head for 4½ perſons a year, minus one buſhel.				
3. Graſſes.				
4. Ditto.				
5. Ditto.				
The whole, without any horſe account, would feed, 1ſt year, three ſheep per acre, 26 weeks 2d two ditto ditto 3d one ditto ditto to the improvement (or the value in keeping) of 40*s*., and for five acres in each to 10*l*.; hence it appears that to keep one horſe would almoſt equal the whole amount.				
6. Rye: 1½ quarter; twelve buſhels; ſeed deducted, ten; ſufficient to ſupport one perſon fifteen months; and for five acres ſix perſons one year and eight weeks - - -	6	1	8	0
Within a ſmall fraction equal to	8	1	0	0
The ſame land in heath would feed, but not fatten, to the value of 10*s*. per acre; call this 20lbs. of mutton; 100lbs. for five acres, and 600lbs. in ſix years; ſufficient, at ½lb. per diem, for three perſons a year and thirty-ſix days -	3	1	5	1

	Perſons.	Years.	Weeks.
Brought forward, arable account -	8	1	0
Deduct, as farms on this ſoil are large, only half a perſon for thirty acres for the farmer; and reckoning labour at 8*s*. an acre, it is 12*l*. for thirty acres, or 2½ perſons; in all three - -	3	1	0
Remain for market - - - -	5	1	0
Graſs for ditto - - - - -	3	1	5

But "a fraction is to be deducted for farmer and ſhepherd. The difference, therefore, is as five to three. But if the barley be conſumed in bread, the account will be,

Barley - - - - - - -	4½	1	0
Together	9½	1	0
Graſs - - - - - -	3	1	5

Conſequently the arable is therefore ſuperior as nearly three to one. Upon the whole of theſe compariſons it is ſufficiently clear, that the arable land is, and in every caſe may be, (by eating barley and oats,) far ſuperior to graſs-land in the article of feeding not only the people at large, but alſo in ſending a ſurplus to market. He cannot, however, let his papers go from his hands without requeſting them to be read with candour. He preſumes to offer them but as rough ſketches, that may approximate to truth, but cannot reach exactneſs: they may afford hints uſeful to future inquirers, and the ſubject is intereſting enough to anſwer well a very careful examination. One obſervation that goes generally to all is too material to be omitted; the production of meat in England is, it is ſuppoſed, of ſmall importance compared with that of corn, becauſe the poor do not live on the former; meat is the conſumption, generally ſpeaking, of thoſe who are in very eaſy circumſtances, compared with the great conſumers of corn; nor would the times be much complained of, whatever the price of meat might be, provided corn were at a reaſonable price. This is a circumſtance which ſhould be conſidered as deciſive of the inquiry; and ſufficient to prove, that the great intereſts of the public demand every poſſible encouragement to tillage ſo given, as ſhall preſerve corn at a fair price, neither too high for the poor, nor ſo low as to diſcourage the cultivation of it by the farmer.

With regard to what ought to be the proportion between the graſs and arable land of a farm, errors are, it is obſerved, extremely common among landlords, and not leſs ſo with farmers: in general, however, they both look to their own intereſt; the firſt to keep much in graſs, and the latter to plough all they can: with ſhort leaſes, and bad covenants, we are not to be ſurprized at either. One acre of moderate corn, ſays Adam Smith, in his Wealth of Nations, yields a greater neat profit than an acre of the beſt paſture. And experience, Mr. Davis of Longleat obſerves, ſufficiently evinces the extreme difficulty of perſuading tenants to believe that they get more, generally ſpeaking, by feeding their lands than by ploughing them; yet it requires very few arguments to convince a landlord, that in cold wet lands eſpecially, the leſs ploughed land you have, the leſs you put it in a tenant's power to ruin your eſtate. That a tenant of 60*l.* per annum in a dairy-farm will get money, while a corn-farm will ſtarve its occupier (though, perhaps, the former gives 15*s.* an acre for his land, and the other but 10*s.*), is ſelf-evident. Perhaps, ſays Mr. Billingſley, in the third volume of the Bath Memoirs, there cannot be a ſtronger proof of the inferiority of the plough, with reſpect to profit, than the ſuperior punctuality of the dairy-farmer in the payment of his rent. He never met with the ſteward of a manor devoted partly to corn and partly to dairy-farms, who controverted this ſtatement.

Clay.—Upon "this ſoil, when tenacious and not eaſily drained, a larger portion ſhould, it is obſerved, be kept in graſs than perhaps on any other; and for this reaſon,—green winter food is not to be gained at all, or, if gained, not without great difficulty and expence; conſequently, the team, and whatever cattle may be kept for conſuming ſtraw and making dung, muſt depend in a larger meaſure on meadow hay, than upon ſoils which admit turnip, cabbage, &c. Clover will do on clay, but it is more hazardous and liable to failure; in which caſe, without a certain reſource in the hay of natural graſs, the farmer would often find great inconveniences. He has examined many farms with this object in view, and found that, when half the land has been graſs, they have been more profitably conducted than with a leſs proportion; but on no account with leſs than one-third."

Loam.—It is ſtated that "one-third or one-fourth in graſs is a proportion found ſuitable to various loams; the more they tend to wetneſs, the larger the portion. It is not, however, eſſential on theſe ſoils, not only becauſe clover and other artificial graſſes are leſs apt to fail; but likewiſe by reaſon of their admitting profitably the alternate huſbandry of graſs and arable."

Sand.—It is contended "that ſome rich ſands are of ſo happy a texture, that they do very well in permanent graſs, and without burning in ſlight droughts; but, in general, it may be obſerved, that ſand in its ſeveral varieties is, of all other ſoils, that which pays beſt in tillage: it is eaſily worked; expences are light; it manures itſelf by agreeing well with ſheep; and, as the reſult of the whole, farmers are uſually rich upon it. In reſpect of the proportion, it is beſt managed, perhaps, when the whole is under the plough; for, by means of cultivated graſſes of proper ſorts, all the ſtock of the farm may be profitably ſupported, and the land reſted ſufficiently, for enſuring a perpetual production of corn. But, contrary to this maxim, and moſt unprofitably, large tracts are commonly tied up from the plough, by covenants of leaſes, under the name of ſheep-walk, heath, &c. which would, by alternate tillage and reſt, produce more corn, and keep more ſheep, than in the preſent ſtate: this is particularly the caſe in Norfolk, Suffolk, Nottinghamſhire, and ſome other counties."

Chalk and Lime-ſtone Soils.—"Nearly the ſame obſervation is to be made on this claſs; they are more productive under the plough than in graſs. But landlords tie up their tenants from ploughing downs in Suſſex, Hampſhire, Dorſetſhire, and Wiltſhire; but in Glouceſterſhire, the Eaſt Riding of Yorkſhire, and Lincolnſhire, they have, on the whole, been leſs tenacious; ſtill, however, large tracts remain, which would be ploughed were tillage permitted. Rules may be carried too far, and this among the reſt. Dorſetſhire has its ewe leaſes, which, in many caſes, ought not to be touched; and fine ſweet downs, which by very attentive management have been brought to a conſiderable degree of fertility, are ſo uſeful to ſheep in winter, that exceptions muſt occur. Another motive for ploughing is the peculiar advantage derived on this ſoil from ſaintfoin, one of the moſt uſeful graſſes that we owe to the bounty of Providence, but attainable only by tillage."

Peat.—Immenſe regions of moors ſpread widely through all the northern counties, and even in the moſt ſouthern, as Devonſhire and Somerſetſhire, Cambridgeſhire and Wales; alſo ſedgy bottoms are found every where. They admit and call for a much greater improvement than any other ſoil, comprehending the larger part of the waſte lands of the kingdom. Theſe ſoils are very rarely brought into the ſtate they are capable of, without tillage, and conſequently, to prohibit it, is to paſs a decree of perpetual ſterility. The obſtacle, however, moſt common on moors is, the rights of commonage, which do not come within the ſcope of the preſent inquiries. When improved, they are commonly much more adapted to graſs than to tillage, not however without numerous exceptions, as we ſee by the general practice in the fens of Cambridgeſhire and Lincolnſhire. The alternate huſbandry does well upon them: it is eaſy, however, to be too buſy with the plough; for, when good graſs is gained, it is the wiſer way to continue it in a productive ſtate.

But it is further ſtated, that the ſubject of the proportion between graſs and arable requires a word or two, viewed in another light, beſides the relation to ſoil. This is the prevalent application of the land. In the midland counties, where grazing very widely extends, it is common to ſee entire farms of graſs-land, and the tenant prohibited from breaking up an acre; in ſuch caſes there is a motive for ploughing not immediately connected with ſoil. To till a part would be right, whatever the ſoil may be; ſtraw, in ſuch a country, is not to be bought, and the convenience and profit of having ſome is no inconſiderable object; it would be carefully uſed as litter, and the manure ariſing would improve a portion of the land. Some cabbages, or Swediſh turnip, or common turnip, might be raiſed (which to a certain extent, and for certain objects on ſuch farms, would be highly valuable to the grazier), ſo as to outweigh large expences in procuring them on ſoils not quite adapted to their culture. There is not a queſtion but a farmer in ſuch caſes could afford to pay more rent for liberty to plough a portion of his land than under the preſent covenants. This would, it is ſuppoſed, extend to a fourth of the farms in ſoil rather unfavourable to the plough; and to a large proportion in others. But even three or four ſmall fields, though no more than one-fifth, one-ſixth, or one-tenth, would be highly advantageous to himſelf and the public, and not at all injurious to the landlord or owner. And to dairy-farms, when entirely in graſs, as many are in Wiltſhire, Glouceſterſhire, and other counties, this remark is yet more applicable, as the produce of tillage, ſtraw, cabbage, &c. is yet more neceſſary than in a mere fattening ſyſtem. In this caſe, and indeed in moſt others, the quantity might be partly regulated by the team: a dairy-farmer, who keeps four horſes to draw his butter or cheeſe to fairs, &c. ought, without queſtion, to have tillage enough to employ thoſe horſes: and it is no difficult matter to aſcertain that quantity. If the various works be examined carefully, it will be found, that a horſe to twenty acres of tillage is a fair proportion, which will leave time for carting hay in ſummer, and the products of the farm in winter. He is not ſpeaking here of tillage farms on ſands, &c. or with rotations of crops, in which the ſoil reſts for ſeveral years: on ſuch the proportion varies: but merely on graſs-farms, where ſome horſes muſt be kept, and are at preſent unemployed a large part of the year. But meadow farms, properly ſo called, are never, to his knowledge, met with but in the vicinity of great cities, where the demand for hay is great and uniform; horſes on ſuch are kept only for the purpoſe of carrying hay to market, bringing dung back, carting the hay to the ſtack, and the manure to the fields. Straw is wanting for litter and for thatch; but it is queſtionable whether it is profitable to plough for this object only in any caſe; a ſcattering of tillage is in ſome places found, but not by any certain rule; the neceſſity is ſmall, and ſtraw uſually to be purchaſed. Such diſtricts, being highly improved, demand very little attention, it is ſuppoſed. See TILLAGE, *Rotation of* CROPS, and PASTURE.

GRASS *Leaſe*, in *Agriculture*, a term frequently applied to ſuch ſward lands as are appropriated to the purpoſes of grazing, or the fattening of neat cattle and ſheep.

GRASS-*Seeds*, a term often uſed to ſignify the ſeveral different ſeeds of graſſes that are employed in laying land down to the ſtate of turf. It was, however, formerly, moſtly made uſe of to denote the mixture of all ſorts of rubbiſh that was ſcraped up from the hay lofts, or collected in the cribs or boxes below the racks in the ſtables. But, in the improved method of forming new graſs lands, the practice of uſing ſuch mixtures of ſeeds is almoſt wholly laid aſide, and only ſuch as are really uſeful and proper, had recourſe to, by which the lands are found to be much more valuable and productive. See *Laying* LANDS *down to Graſs*.

GRASS-*ſods*, in *Rural Economy*, a name applied to ſuch ſods or turfs as are pared off from the ſurface of old ſward-lands, whether they be intended for the purpoſe of burning on the land, for fuel, or for being laid down in order to form a lawn, or ſmall plot of fine even turf. In the former intentions they are generally pared off by ploughs, or ſpades, contrived for the purpoſe; but in the latter almoſt conſtantly with great regularity and exactneſs, by a turf ſpade for the purpoſe. A tool of the plough kind ſeems, however, capable of being employed in this way alſo with advantage. See the next article.

GRASS-*ſod-cutting Plough*, the name of a tool of the plough kind, which was invented on the continent by count Van Mattzen, and which has been highly uſeful in cutting graſs-ſods in a cheap and expeditious manner. It can alſo be had recourſe to with great advantage in paring the ſwards off old graſs lands, waſtes, and commons, previouſly to their being burnt and brought into the ſtate of tillage-huſbandry. It is likewiſe capable of being converted to the purpoſe of forming walks in grounds where they may be wanted, as well as in paring the bottoms and ſides of them, and of ſuch as have been already made, by which means the gardener will only have the ſimple buſineſs of raking and rolling them to perform.

By ſome ſlight alterations in the manner of placing the coulters, graſs ſods are likewiſe capable of being cut in a very ready manner, and in any form that may be required, ſo as to be employed in the conſtruction of banks, fortifications, huts, and other works of a ſimilar kind. It would ſeem, conſequently, to be a very uſeful tool in the expenſive buſineſs of conſtructing embankments againſt the ſea, or other large waters.

The inventor was led to the conſtruction of this plough, in conſequence of the want of a more cheap and expeditious method of performing the work than the uſual one of the ſpade, in cutting turfs for forming graſs-plats, &c.

It may be obſerved that in forming the tool, the beam, or fore part of any common plough will anſwer the purpoſe; this part is conſequently not repreſented in the figure, the hind or operative parts being ſimply ſhewn. The tool is capable of being managed by any perſon who is able to direct a common plough.

This plough may be ſeen at *fig.* 7. in the *Plate* on *Grazing*, in which the nine holes ſhewn by A, A, in the beam, ſerve, as in the common plough, to regulate the length of the beam merely by placing the pin C forwards or backwards, and thereby to make the cutting-iron to work to greater or leſs depth. The two coulters, E, E, which are placed on each ſide of it, in front of the cutting-iron D, ſerve to guide the ſide cut, preparatory to the ſeparation of the turf or ſod. The cutting-iron D may, by means of the ſcrews G, G, be raiſed or lowered at diſcretion. And, in order to keep it in its place properly, the two ſupports at H, are made, and provided with ſeveral holes for the purpoſe at I, formed in the cutting-iron D. The two handles are diſplayed at K, K, and the frame at L L L L; the whole of the remainder, which in the frame is marked black, is to be formed of iron.

A certain degree of practical experience is neceſſary, in order to uſe this plough, ſo as to form the turfs with exactneſs; and in the commencement of the work care ſhould be particularly taken that the workman does not cut the turfs too deep, and that the plough be not injured by his inattention. In a very ſhort time, he will, however, be ſo accuſtomed to the buſineſs as to perform with great exactneſs. In ſetting out the work, a breadth equal to the width of the two cutters ſhould be previouſly cut out, as by that means the cutting-iron takes the ſod at a proper depth, and executes the work, as ſoon as the draught commences, in the team. In the performance of the work, oxen are recommended as preferable to horſes, from their drawing more ſteadily, and being more readily managed on ſtiff lands; but we apprehend that this will not, in general, be found to hold good, and horſe-teams are far more expeditious. See TEAM.

GRASS, in *Mining*, ſignifies the natural ſurface of the earth over a mine; ſometimes alſo it is called "the day," or the top; and a mineral vein appearing on the ſurface, is ſaid to come, or appear to graſs, or to the day. Coals and other ſtratified minerals, when they come to the ſurface, are ſaid to baſſet, crop, burſt-out, go-out, to want-cover, to run-out, to out-burſt, to head-out, to run-out, &c.

GRASS *River*, in *Geography*, a river of America, in the N.W. part of the ſtate of New York, which riſes near the main branch of Black river, and runs N.N.W. about 50 miles, then N.E. 40 miles, and is loſt in the river St. Laurence. N. lat. 45° 12′. W. long. 74° 48′. It is a rapid river, affords many mill-ſeats, and near the mouth, its banks produce great quantities of hay.

GRASSE, a town of France, and principal place of a diſtrict, in the department of the Var. The place contains 12,521, and the canton 13,554 inhabitants, on a territory of 100 kiliometres, in four communes. The principal trade of the town conſiſts in dry fruit, olives, oil, perfumes, and tanned leather:—9 miles W.N.W. of Antibes. N. lat. 43° 39′. E. long. 6° 59′.

GRASSE, *La*, a town of France, in the department of the Aude, and chief place of a canton, in the diſtrict of Carcaſſone; 20 miles S.W. of Narbonne. The place contains 1123, and the canton 4524 inhabitants, on a territory of 292½ kiliometres, in 18 communes. N. lat. 43° 5′. E. long. 2° 42′.

GRASSES, *Petrified*. Mr. Whitehurſt, in his "Inquiry concerning the Earth," 1ſt edit. p. 169, mentions graſſes among the vegetable remains in the coal-meaſures of Derbyſhire: but the late Mr. William Martin, who was perhaps better acquainted with theſe ſtrata, ſays, "Outlines," p. 85, that the gramina of theſe argillaceous ſtrata are of unknown ſpecies in the recent ſtate, and appear rather allied to the canes and reeds of the Indies, than to graſſe properly ſo called. Mr. Farey alſo, in his laborious reſearches among theſe carboniferous ſtrata, has ſeen nothing reſembling graſſes imbedded in them. See Reeds.

In peat diſtricts, which are of modern or recent accumulation, and within the range of flooded rivers, it is not uncommon to meet with preſerved graſſes, probably belonging to many of the recent ſpecies, at conſiderable depths below the ſurface of, or even at the bottom of the peat, or muddy depoſits; but ſuch peat foſſils ſhould on all occaſions be diſtinguiſhed carefully from ſtratified, or real foſſil remains, as remarked in our article Coal.

GRASSHOPPER, in *Entomology*, a ſpecies of *Gryllus*; which ſee.

Grasshopper, in *Ornithology*, a name given to the *Alauda trivialis*; which ſee.

GRASSI, Cecilia, in *Biography*, afterwards Mrs. Bach, who performed the firſt woman's part for ſeveral ſucceſſive years at the opera with Guarducci and Guadagni, was inanimate on the ſtage, and far from beautiful in her perſon; but there was a truth of intonation, with a plaintive ſweetneſs of voice, and innocence of expreſſion, that gave great pleaſure to all hearers who did not expect or want to be ſurpriſed. Her performance of the part of Euridice, in Gluck's "Orfeo," with Guadagni, was perfect in all reſpects, and gave univerſal ſatisfaction.

GRASSWINKEL, Theodore, a learned lawyer and writer, who flouriſhed in the 17th century, was a native of Delft. He wrote various works upon legal and political ſubjects, by which he acquired a conſiderable reputation, and was regarded by the government as a proper perſon to fill ſome office in the ſtate; he was accordingly made fiſcal of the domains of the ſtates of Holland, and ſecretary of the bipartite chamber on the part of the ſtates-general. He died in 1666, at Mechlin, and was buried in the great church at the Hague. His works were numerous: of theſe the following may be noticed, "Libertas Veneta, ſeu Venetorum in ſe et ſuos imperandi Jus." This was publiſhed in 1634, and in 16[illegible] he defended the republic of Venice, in a diſpute with the duke of Savoy concerning precedence. For theſe ſervices, that republic created him a knight of St. Mark. Previouſly to the publication of the laſt of the two above-named works, he attempted to confute the popular maxims of Buchanan, in a treatiſe, entitled "De Jure Majeſtatis." This was dedicated to Chriſtina, queen of Sweden, who was known to be a great aſſertor of regal privileges. Graſswinkel defended the liberty of the ſeas againſt a native of Genoa, in his work "Maris Liberi Vindiciæ." He was author, likewiſe, of a treatiſe in two volumes 4to. "On the Sovereignty of the States of Holland." He was at all times a defender of particular ſtates; but a violent oppugner of the rights of the people. Moreri. Bayle.

GRATAROLUS, William, was born at Bergamo, in Italy, in the year 1510. He was educated at Padua, where he took the degree of doctor of phyſic, and afterwards became profeſſor of the ſame ſcience, and gained conſiderable diſtinction. But having embraced the Calviniſtic doctrines, on the perſuaſion of Peter Vermilli, he fled from Italy, through fear of the inquiſition, and retired to Marpurg, where he taught medicine for a year. But he was compelled to leave that place alſo, and repaired to Bâle, in the hope of a better fortune, and where, in fact, he taught and practiſed his profeſſion with ſucceſs, until May 1562, when he died, at the age of 52. He was author of a great number of works, ſome of which are honourable to his talents, and evince a large ſhare of knowledge; but in others he ſhews an attachment to the abſurdities of the alchemiſt, much ſuperſtition, and opinions which do not imply a ſound judgment. Eloy. Dict. Hiſt.

GRATCHI, in *Geography*, a town of Ruſſia, in the country of the Coſſacks; 20 miles N.W. of Tzaritzen.

GRATIAN, in *Biography*, a Roman emperor, ſon of Valentinian I. was born at Sirmium, in 359. He was appointed by his father to a ſhare in the empire when he was but eight years old. He was in his ſeventeenth year when Valentinian died. At this time Gratian was keeping his court at Treves, and was ignorant of what had happened till he was informed that the officers of the army had appointed as his partner in the throne Valentinian II. the younger ſon of the late emperor, by his ſecond wife Juſtina. Gratian, though hurt at the aſſumption of authority on the part of the army, readily ratified the election, and ever treated his brother with affection and tenderneſs. The Weſtern empire was nominally divided between them, but the ſuperior age of Gratian gave him all the power. One of his firſt acts was to recal his mother to court, who had been divorced and baniſhed; and this act of juſtice was followed by the puniſhment of certain officers in the ſtate, who had abuſed their power, by cruelty and injuſtice. While the emperor is praiſed for theſe deeds, he has not eſcaped blame, and a high degree of cenſure, for putting to death the renowned general Theodoſius, who fell a victim to the jealouſy of ſome rival courtiers. Hiſtory has alſo cenſured him for the indulgence which he afforded to the clergy, and for his ſeverity againſt thoſe who were denominated heretics, for the gratification of the orthodox. At the head of the Eaſtern empire was his uncle Valens, who was in 378 attacked by the Goths. Gratian, active and courageous, put himſelf at the head of an army, and marched to his aſſiſtance. He obtained a deciſive victory in Alſace, and, purſuing his ſucceſſes, croſſed the Rhine, and penetrated into the heart of the enemy's country, in order to join the forces of Valens. Before, however, he could reach him, that emperor had been defeated and ſlain at the battle of Adrianople. Gratian now felt that he muſt take the moſt vigorous meaſures againſt their common enemy, and immediately called from his retreat Theodoſius, ſon of the general who had ſuffered under his haſty diſpleaſure, and placed him at the head of a ſeparate army, with which he was enabled to deſtroy a large body of Sarmatians, who were on their march to join the Goths. Gratian himſelf proceeded to Conſtantinople, where he recalled thoſe orthodox biſhops who had been baniſhed by Valens, and he alſo iſſued ſome edicts relative to the exerciſe of religion. As Valens had left no male heirs, his nephew, diſregarding the ſuggeſtions of perſonal ambition, filled the vacant throne to the ſatisfaction of all, by raiſing Theodoſius to a ſtation, for which his talents were peculiarly adapted. This was in the year 379, after which Gratian returned to Italy, and in his journey he had an opportunity of being benefited by the inſtructions of the celebrated Ambroſe, at Milan, which proved beneficial to the orthodox, but occaſioned new reſtrictions upon thoſe who were regarded as ſectaries. After this he continued for ſome length of time to attend to the defence and concerns of the empire, and is highly applauded for almoſt all the amiable qualities which have decorated the beſt of ſovereigns. Still it was feared that his good principles were rather the effect of able and virtuous adviſers, than the ſpontaneous reſult of fixed habits. What the beſt friends to their country feared, proved to be the real fact: he ſuddenly fell into ſnares of unmanly pleaſures, ſpent much of his time in indolence or frivolous amuſements, which proved not only injurious to his ſubjects, but, in the end, ruinous to himſelf. Hunting became his favourite paſtime: to enjoy the purſuits of the chace, he neglected the duties incumbent upon him, as the ſovereign of a great people, and thoſe only became his favourites who were ſkilful in hunting. He offended the more ſober part of his ſubjects, by appearing in the garb of a Scythian warrior, armed with a bow and quivers, and diſcontents were on the very point of embodying themſelves into a ſerious ſhape, when a revolt took place among the legions of Britain, who, without heſitation, inveſted Maximus with the imperial diadem. Gratian attempted an oppoſition; but his own efforts were feeble, and theſe even were counteracted by the treachery of ſome of his officers. He had no ſooner unfurled his banners, and put himſelf in a warlike poſture, than he was deſerted by his houſhold troops. He had now no hope, and immediately fled with about 300 faithful troops towards the Alps. All the cities on his road manifeſted evident ſigns of diſloyalty: they even refuſed him a ſhelter or admiſſion into their towns, till he arrived at Lyons. Here, indeed, the gates were opened for his reception, but the hearts of the people were eſtranged to his cauſe, and upon the arrival of the cavalry of Maximus, the governor of the city betrayed the depoſed emperor into the hands of the commander, who cauſed him to be put to death, as he roſe from his ſupper. This was in the year 383, after Gratian had been on the throne nearly eight years. Gibbon. Univer. Hiſt.

GRATIAN, a Benedictine monk, who flouriſhed in the twelfth century, was a native of Chiuſi, in Tuſcany, and embraced the monaſtic life at Bologna. Before his time, there had been many collections of canons and laws of the church, but they were ſo defective in matter and form, that they could not be conveniently explained, or even made uſe of as ſyſtems of eccleſiaſtical polity. Gratian undertook the taſk of compiling ſuch a ſyſtem, and after more than twenty years' labour he produced, in 1151, an abridgment of canon law, drawn from the letters of the pontiffs, the decrees of the councils, and the writings of the ancient doctors, which he entitled "Concordantia diſcordantium Canonum," or as it has been tranſlated, "The Coalition of jarring Canons" In a new edition of this work, it was called "Decretum Gratiani," or "Gratian's Decretal." By this name it is generally known. Upon the firſt appearance of the work, it received the ſtamp of approbation from pope Eugenius III., who declared himſelf ſo ſatisfied with its execution, that he commanded it to be publicly read in the ſchools. The profeſſors of Bologna were the firſt who unanimouſly adopted it as a text book in their public lectures, and their example was ſoon followed by the profeſſors of Paris, and, in ſhort, by thoſe of almoſt all the European colleges. It is, however, ſaid to be full of errors, and in other reſpects extremely defective, but as it was calculated to ſupport deſpotiſm, and to extend the authority of the Roman pontiffs, it was for four centuries appealed to as the ſtandard of eccleſiaſtical law, and even in ages ſucceeding that dark period, it has occaſionally been quoted with a degree of veneration and authority, to which it has no juſt title. It was uſed in MS. till 1472, when it was printed at Mentz: this edition was followed by impreſſions at Venice in 1476, and Paris in 1508. Another edition was printed at Rome under the auſpices of pope Gregory XIII. in four vols. fol. on which a large portion of labour was beſtowed in correcting its numerous imperfections. Anthony Auguſtin, archbiſhop of Tarragona, in Spain, publiſhed a valuable treatiſe "De Emendatione Gratiani," of which the beſt edition is that publiſhed at Paris in 1672. Moreri.

GRATICULATION, a term ſome writers uſe for the dividing a draught or deſign into ſquares, in order to the reducing it thereby.

GRATINGS, in a *Ship*, are ſmall ledges of ſawed plank, framed one into another like a lattice or priſon grate, lying on the upper deck, between the main-maſt and fore-maſt, ſerving for a defence in a cloſe fight, and alſo for the coolneſs, light, and conveniency of the ſhip's company.

GRATIOLA, in *Botany*, the diminutive of *gratia*, a grace or favour, the herb to which it is applied having been called, by the earlier botanical or medical writers among the moderns, *Gratia Dei*, *the favour of God*, becauſe of its eminent virtues, which however are of a violent and cathartic nature. It is one of the plants which have been conjectured to yield the tincture called *eau medicinale*, ſo famous at preſent as a cure for fits of the gout, but this opinion, it ſeems, is contradicted by the proprietor of the ſecret.—Linn. Gen. 13. Schreb. 17. Willd. Sp. Pl. v. 1. 102. Vahl. Enum. v. 1. 88. Mart. Mill. Dict. v. 2. Ait. Hort. Kew. ed. 2. v. 1. 42. Brown. Nov. Holl. v. 1. 435. Juſſ. 121. Lamarck. Illuſtr. t. 16. Gærtn. t. 53?—Claſs and order, *Diandria Monogynia*. Nat. Ord. *Perſonatæ*, Linn. *Scrophulariæ*, Juſſ.

Gen. Ch. *Cal.* Perianth inferior, in five deep, awl-ſhaped or ovate, upright, permanent ſegments. *Cor.* of one petal, tubular, unequal; tube longer than the calyx, angular; limb ſmall, in five deep ſegments, of which the uppermoſt is broadeſt, emarginate and reflexed, the reſt ſtraight and equal. *Stam.* Filaments four or five, awl-ſhaped, ſhorter than the corolla, the two or three lowermoſt ſhorteſt and barren, the two uppermoſt attached to the tube of the corolla; anthers roundiſh. *Piſt.* Germen ſuperior, conical; ſtyle ſtraight, awl-ſhaped; ſtigma with two lips, cloſed after impregnation. *Peric.* Capſule ovate, pointed, of two cells and four valves, the partition from the inflexed margins at two oppoſite ſides. *Seeds* numerous, ſmall.

Eſſ. Ch. Corolla irregular, reverſed. Two ſtamens barren. Capſule ſuperior, of two cells and four valves. Calyx in five deep ſegments. Stigma with two lips.

Linnæus's *gratiola*, in the firſt edition of Sp. Pl. 17, chiefly depended on the original and primary ſpecies, the *officinalis*, for of the three others there defined, *dubia* is *Capraria gratioloides* of the ſecond edition, and *Lindernia pyxidaria* of his Mantiſſa 252; *virginiana*, though in his poſſeſſion, was made a *Gratiola* chiefly on Gronovius's authority; and *peruviana*, though a genuine *Gratiola*, had then probably never been ſeen by Linnæus at all, but was adopted from Feuillée. In the ſecond edition *G. Monnieria* takes place of the *dubia*, and a wrong Eaſt Indian ſynonym is annexed to *virginiana*, but no further ſpecies are added. In the ſecond Mantiſſa two new ones are deſcribed, *rotundifolia* and *hypopoides*, both from the Eaſt Indies, ſo that ſix ſpecies in all are enumerated in Syſt. Veg. ed. 14. To theſe Willdenow has added eight more, chiefly Eaſt Indian, prudently declining to adopt three unſeen ones from Walter's Flora Caroliniana. Vahl has far outſtepped his predeceſſors, giving 31 ſpecies in all. Unfortunately a great ſhare of theſe were deſcribed from dried ſpecimens, their genus determined chiefly by habit, and their flowers or fruit not ſufficiently inveſtigated. Indeed ſeveral of them evidently differ from the original genus in various reſpects. Mr. R. Brown, a more critical inveſtigator, has greatly reduced the genus in queſtion, though he has deſcribed three entirely new ſpecies from New Holland. We ſhall confine ourſelves to an account of ſuch as are certain, with compendious remarks on a few of the reſt.

1. G. *officinalis.* Linn. Sp. Pl. 24. Fl. Dan. t. 363. Woodv. Med. Bot. t. 47. Bulliard t. 130. Ehrh. Pl. Off. 11. (Gratiola; Matth. Valgr. v. 2. 58. Rivin. Monop. Irr. t. 106.)—Leaves ovato-lanceolate, ſerrated, five-ribbed, ſmooth, ſomewhat longer than the flower-ſtalks.—Native of moiſt places in Denmark, Germany, Switzerland, France, and Greece, flowering in June. The *roots* are perennial, rather creeping. Whole *herb* ſmooth. *Stems* annual, aſcending or erect, twelve or eighteen inches high, leafy, round, pale and very ſleek, generally ſimple. *Leaves* numerous, oppoſite, ſeſſile, dotted, above an inch long, ovato-lanceolate, bluntiſh, with many ſhallow tooth-like ſerratures in the upper part, and five, rarely ſeven, parallel ribs, of which the middle one is the moſt conſiderable. *Stipulas* none. *Flowers* pale lilac, with an orange tube, inodorous, ſcarcely an inch long, on ſimple, ſolitary, axillary ſtalks, which are generally about half the length of the leaves, often *more*, and bear a pair of bracteas cloſe to the flower, by ſome taken for additional parts of the calyx; theſe are ſpreading and a little toothed.—This ſpecies, a ſtranger to Britain, is the original one, celebrated for its purgative virtues, whence the French call it Poor-man's herb, on account of its cheapneſs and efficacy. Indeed its uſe requires great caution, and a plentiful adminiſtration of warm water, butter, or oil, at the ſame time. A ſcruple of the dried herb is mentioned as a ſufficient doſe, but its uncertainty, and its emetic properties, have juſtly brought this medicine into diſuſe; there being ſo many more unexceptionable drugs for the ſame purpoſe. Its flavour is nauſeous and intenſely bitter.

2. G. *piloſa.* Mich. Boreali-Amer. v. 1. 7. Vahl. n. 16. (G. peruviana; Walt. Carol. 62.)—Leaves ovate, crenate, hairy as well as the ſtem. Flowers axillary, nearly ſeſſile.—Native of moiſt places in South Carolina, flowering in May. *Stem* ſimple or branched, near a foot high, ſquare, leafy, very hairy. *Leaves* ovate, not an inch long, ſomewhat heart-ſhaped and claſping the ſtem with their baſe, bluntiſh, with two or three diſtant teeth on each ſide, fringed, dotted, and hairy. *Flowers* nearly ſeſſile, white, with a pair of ſpreading bracteas, which are fringed like the calyx.

3. G. *peruviana.* Linn. Sp Pl. 25. (G. latiore folio, flore albo; Feuill. Peruv. v. 3 23. t. 16.)—Leaves ovate oblong, toothed, downy, obſcurely five-ribbed. Flowers axillary, ſeſſile.—Native of Peru, Mexico, and the Brazils. The whole herb is more or leſs downy. *Stem* a ſpan high, angular, moſtly ſimple. *Leaves* oblong, ſomewhat ovate, various in breadth, bluntiſh, obſcurely five-ribbed, the margin furniſhed with diſtant teeth. *Flowers* white, nearly or quite ſeſſile, ſhorter than the leaves, with a pair of bracteas very like, and about equal to the calyx, ſtrongly countenancing the idea of their being properly calyx-leaves.

4. G. *latifolia.* Brown n. 1.—"Smooth. Leaves ovate, obtuſe, obſcurely crenate or entire. Flowers ſeſſile."—Native of the neighbourhood of Port Jackſon, New South Wales, and of Van Diemen's land.

5. G. *pubeſcens.* Brown n. 2.—"Clothed with glandular hairs. Leaves lanceolate, toothed. Flowers nearly ſeſſile."—Native of Port Jackſon, the ſouth coaſt of New Holland, and Van Diemen's land.

6. G. *pedunculata.* Brown n. 3.—"Clothed with powdery down. Leaves lanceolate, toothed in their forepart, ſcarcely longer than the flower-ſtalk."—Native of Port Jackſon.

Mr. Brown announces the exiſtence of a few unpubliſhed ſpecies, natives of North America, of which we know nothing further. He mentions the Linnæan *G. hypopoides* and *rotundifolia* as ſpecies of *Lindernia* with two barren ſtamens, undoubtedly a variable circumſtance in this tribe, and conſtituting no generic diſtinction. *G. Monnieria* is his *Herpeſtis*, and has the appearance of a good genus.

With reſpect to ſome other ſpecies.

G. *linifolia.* Vahl. n. 4. (Digitalis linifolia luſitanica paluſtris; Tourn. Inſt. 165.)—"Leaves linear, entire. Flower-ſtalks axillary, the length of the leaves."—Native of Portugal. This ſeems an unqueſtionable *Gratiola*, near the *officinalis*, with which it agrees in qualities, but differs in leaves, and in the flowers not being more than one-third the ſize of that ſpecies.

G. *lobelioides* of Retzius, Vahl. n. 10, has neither the habit, calyx, nor bracteas of this genus.

G. *trifida.* Willd. n. 9, ſeems to agree in all thoſe points with Mr. Brown's *Limnophila*, the *Hottonia indica* of Linnæus.

G. *lucida.* Vahl. n. 17. (*Capraria cruſtacea* of Linnæus), is referred by Mr. Brown to *Torenia*, a genus hitherto not much underſtood.

Gratiola *Officinalis*, *Hedge-Hyſſops*, in the *Materia Medica*, is a plant to which various medical virtues have been aſcribed. The firſt account of its cultivation in Britain, is that given by Turner in 1568, though it is ſaid that the firſt botaniſt who mentioned it was Matthiolus. It has a ſtrong bitter nauſeous taſte, with but little or no odour; and its virtues are extracted more perfectly by aqueous than by ſpirituous menſtrua. It reſembles digitalis both in the ſhape of its flowers, and in its medicinal effects, and hence has been called Digitalis minima. It is certainly a powerful and active cathartic, and operates ſo violently as generally to induce vomiting; and on this account, Chomel thought it to be a medicine adapted only to the more vigorous and robuſt conſtitutions. Many others, however, recommend it as a ſafe and uſeful purgative. But as its effects are uncertain, it ſhould be adminiſtered with the precaution of a gradual increaſe of its doſe. This plant has been commonly uſed in hydropical caſes; and in moderate doſes it is ſaid not only to act as a hydragogue, but alſo to manifeſt a diuretic character; and inſtances of its good effects in aſcites and anaſarca are related by many reſpectable practical writers. Geſner and Bergius found a ſcruple of the powder to be a ſufficient doſe, as in this caſe it frequently excited nauſea or vomiting; others have given it to half a dram, two ſcruples, a dram, and even more. The extract is ſaid to be more efficacious than the plant itſelf, and exhibited in the doſe of half a dram or a dram in dyſenteries, produces the beſt effects. Koſtrzewſki informs us, that in the hoſpitals at Vienna, three maniacal patients were perfectly recovered by its uſe; and in the moſt confirmed caſes of lues venerea, it effected a compleat cure. It uſually acted by increaſing the urinary, cutaneous, or ſalivary diſcharges. Woodv. Mat. Med.

GRATIOSA, in *Geography*, one of the ſmalleſt Canary iſlands. N. lat. 29° 15′. W. long. 13° 17′.—Alſo, one of the Azores iſlands, about 10 miles long and eight broad. It takes its name from its beautiful appearance, and fertility in corn, fruit, paſture, and cattle, with which it ſupplies Tercera, and ſeveral of the other iſlands. It is well peopled, and has a number of villages; and the coaſt is defended by forts. The chief place is La Plata. N. lat. 39° 2′. W. long. 27° 56′.

GRATITUDE, in *Ethics*, a virtue diſpoſing the mind to an inward ſenſe and outward acknowledgment of benefits received. This is a virtue in which the Egyptians pretended to excel all the reſt of mankind. See Egypt.

GRATIUS, in *Biography*, a Roman poet, ſurnamed from the place of his birth Faliſcus, was a contemporary of Virgil. They are both mentioned by Ovid in a ſingle diſtich. The work by which this author is known, and for which he claims a ſhort notice, is entitled "Cynegeticon," or the Art of hunting with Dogs. It was entirely unknown to the moderns till it was brought to light by Paul Manutius in 1534. This learned editor printed it from a MS. copy brought by Sannazaro from France. It is ſaid to be written with a purity not unworthy of the Auguſtan age. The beſt edition is that of Leipſic 1659, 4to. with notes. It has been printed in the collection of "Rei Venaticæ Scriptores," 1728, and in Mattaire's "Corpus Poetarum." Gen. Biog.

GRATTAN, in *Agriculture*, a term applied provincially in ſome ſituations to ſuch arable lands as are managed under a commonable ſtate. But in other places, as in Cornwall, it is employed to ſignify the mowing of graſs the firſt year, after the ground has been manured with ſea ſand; which is an operation that they denominate mowing in grattan. The ſtubbles of common fields are alſo frequently called grattans.

GRATZ, or Graz, in *Geography*, a town of the duchy of Stiria, on the river Muehr; containing ſeveral churches and convents, an arſenal, a caſtle on a rock, and an univerſity founded in 1585. In this town is held the aſſembly of the ſtates; and in 1784, it was erected into an archbiſhopric on the ſuppreſſion of that of Goritz. It is ſurrounded by walls. The French took it in 1797; 70 miles S.S.W. of Vienna. N. lat. 47° 10'. E. long. 15° 16'.—Alſo, a town of Sileſia, called alſo *Hradetz*, in the principality of Troppau, ſituated on the Mora; four miles S. of Troppau. N. lat. 49° 47'. E. long. 17° 50'.

GRATZEN, a town of Bohemia, in the circle of Bechin; 37 miles S.S.E. of Bechin. N. lat. 48° 47'. E. long. 14° 43'.

GRAVA Sele, a town of Naples, in the Baſilicata; 15 miles E. of Venoſa.

GRAVATTEN, a town of Pruſſia, on the Curiſch Nerung; 20 miles S. of Memel.

GRAUDENTZ, a town of Pruſſia, in the palatinate of Culm, on an iſland near the Viſtula; anciently called Grodek; 14 miles N. E. of Culm. N. lat. 53° 28'. E. long. 18° 28'.

GRAVE, in *Grammar*, a ſpecies of accent oppoſite to acute. The grave accent is expreſſed thus (`); and ſhews that the voice is to be depreſſed, and the ſyllable over which it is placed pronounced in a low, deep tone.

Grave, in *Muſic*, is applied to a ſound which is in a low or deep tone.

The thicker the chord or ſtring, the more grave the tone or note, and the ſmaller the acuter.

Notes are ſuppoſed to be the more grave, in proportion as the vibrations of the chord are leſs quick. See Gravity, in *Muſic*.

Grave is alſo an ingredient in the compoſition of divers terms in hiſtory and policy. Thus we ſay *land-grave*, *burg-grave*, *marg-grave*, *pals-grave*, &c.

The word, in this ſenſe, is formed of the German *graf*, ſignifying *comes*, *count*; called in the barbarous Latin *gravio* and *graphio*.

Grave is alſo uſed for a tomb, wherein a perſon defunct is interred.

Grave, Ital. (pronounced *graavay*) an adverb applied to ſlow movements in the ſecond degree, more quick than *adagio*, and more ſlow than *largo*. In adagio movements, the time is uſually counted by quavers, in grave, by crotchets. *Grave*, Ital. and *gravement*, French, not only imply a ſlow time, but a certain *gravity* in the execution.

Grave, in *Geography*, a ſtrong town of Brabant, belonging to Holland, ſituated in a marſhy country, on the S. ſide of the Meuſe; 34 miles S.E. of Utrecht. N. lat. 51° 46'. E. long. 5° 41'.

Grave *Creek*, a creek on the Ohio in Virginia, 12 miles from Wheeling. N. lat. 39° 46'. W. long. 80° 55'. Near this creek is a mound of earth, evidently the work of art, called an Indian grave. Although no tradition remains, that the Indians buried their dead in this manner, theſe mounds, on examination, have been found to contain a chalky ſubſtance, ſuppoſed to be bones of the human kind.

Grave *Harmonic*, in *Muſic*, is a phenomenon thus deſcribed by the late Dr. Robiſon: "The reinforcements of ſound, which are called *beatings*, are noiſes. If any noiſe whatever be repeated with ſufficient frequency, at equal intervals, it becomes a muſical note of a certain determinate pitch. If it recurs 60 times in a ſecond, it becomes the note C-*fa-ut*, or the double octave below the middle *c* of our harpſichords, or the note of an open pipe eight feet long. Now there is a ſimilar (we may call it the very ſame) reinforcement of ſound in every concord. Where the pulſe of one ſound of the concord biſects the pulſe of the other, the two ſounds are more uniformly ſpread; but where they coincide, or almoſt coincide, the condenſation of one undulation combines with that of the other, and there comes on the ear a ſtronger condenſation, and a louder ſound. This may be called a *noiſe*; and the equal and frequent recurrence of this noiſe ſhould produce a muſical note. If, for inſtance, *c* and *a* are ſounded together; there is this noiſe at every third pulſe of *c*, and every fifth pulſe of *a*; that is, 80 times in a ſecond. This ſhould produce a note which is a 12th below *c* and a 17th below *a*; that is, the double octave below *f*, which makes 320 vibrations in a ſecond. That is to ſay, along with the two notes *c* and *a* of the concord, and the compound ſound which we call *the concord of the* VI*th*, we ſhould hear a third note FF in the baſs. Now this is known to be a fact, and it is the *grave harmonic* obſerved by Rameau and Tartini about the year 1754, and verified by all muſicians ſince that time."

Mr. John Gough gives the following account of grave harmonics. "When two ſounds are heard in concert, the vibrations producing them are arranged in cycles, no one of which continues for a longer or ſhorter time than the reſt; and their effect is perceived by the ear, which becomes ſenſible of their preſence. For when each cycle of a ſeries, ſeparately conſidered, exceeds the twelfth part of a ſecond, the ſenſe of hearing recognizes each point of diviſion made by the coincidence of the vibrations which ſeparate the contiguous cycles; this circumſtance enables the ſenſe to contemplate theſe periods apart, and comprehend their origin. On the contrary, when the duration of a cycle belonging to a compound ſeries does not exceed the twelfth part of a ſecond, the interval proves too ſmall to be meaſured by the ear: it therefore eſcapes notice in a ſeparate ſtate; for the points of diviſion recur too frequently to be obſerved. When the auditory organ finds itſelf in circumſtances anſwering to the preceding deſcription, it has but one method to purſue; which is, to treat theſe derivative intervals in the ſame manner it treats all periods, which are ſingly too ſmall for its comprehenſion; it therefore reduces them to a ſimple muſical ſound, correſponding in pitch to a ſtring which vibrates once in the time of each ſucceſſive cycle. A grave harmonic is on this account always a lower note than any of its conſtituents, ſeeing the time of a cycle exceeds the greateſt vibration that enters into the compoſition of it. The ſtrength of a grave harmonic is alſo weak, when compared with the notes compoſing it, becauſe theſe ſecondary ſounds, being nothing more than certain unavoidable efforts of the imagination, they aſſume the character of a feeble ſound, which is juſt ſtrong enough to be heard in the company of one or more louder tones; for the power of the imagination is always inferior to external impreſſions, except in fits of inſanity, when the organs of ſenſe appear to be blunted by phyſical cauſes. The grave harmonics *always keep the direction of the ears*, let the poſition of the head be changed as often as you pleaſe, reſembling in this circumſtance a ſhrill piping note, called the ringing of the ears; which every one aſcribes to a ſlight affection of the auditory duct, becauſe it differs from external ſounds, in having no fixed direction. The grave harmonics agree with the ringing of the ears in this remarkable particular; which is a ſtrong proof that their immediate cauſe is ſeated in the perſon of the hearer; and it is evident from the nature of things, that this cauſe originates in the mind." Nicholſon's Journal, 8vo. vol. iv. p. 2.

We have been thus particular in quoting from two very able writers on the ſubject of the grave harmonics, or Tartinian ſounds, in order to ſhew the foundation of the rules which we ſhall here give, for determining the grave harmonic of any given perfect conſonance, *viz.*

1ſt. Find the number of vibrations made in one ſecond of time by each of the given ſounds: which, ſuppoſing C-*ſol-fa-ut*, or *c* of the German tablature, or that on which the tenor cliff is placed, to make two hundred and forty complete vibrations, is obtained, by multiplying this number by the larger term of the ratio of the given ſounds to C, and dividing the product by the ſmaller term of that ratio, if the given ſounds lie above C, or the reverſe if below it.

2d. Having thus obtained the vibrations of the given conſonance, divide the larger number of them, by the larger term of the given conſonance, and the ſmaller number by the ſmaller term, each of which, if the operation be rightly performed, will give the ſame reſult, and ſhew the number of coincidences of the pulſes of the two given ſounds in one ſecond, and alſo the vibrations in that ſame period, of the grave harmonic ſought.

3d. Compare the number of vibrations laſt found with each of the vibrations of the given conſonance, and reduce their ratios to the loweſt terms, which will then expreſs the intervals or diſtances of the grave harmonic, below each of the given ſounds.

By way of examples of theſe rules, we ſubjoin the following table, ſhewing the grave harmonic, and ſeveral other uſeful particulars, of the principal conſonances in the octave, above C-*ſol-fa-ut*.

Given Conſonances.				Grave Harmonics, or Implied Sounds.								

The experiments of M. Tartini, the diſcoverer of theſe ſounds, extended to ten of the conſonances in our table above, *viz.* the V, 4th, III, 6th, 3d, VI, II, II`, (ſecond minor,) 2d, (greater ſemitone,) and minor ſemitone ($\frac{24}{25}$), but in all of which he ſeems to have miſtaken an octave, in aſſigning the place of the harmonic in the ſcale, and has mentioned each of them as being higher by an octave than in our table. Mr. John Holden, the author of "An Eſſay towards a rational Syſtem of Muſic," printed at Edinburgh in 1807, p. 352, ſeems to have been aware of this latter circumſtance, but in page 350, lays down an inapplicable and falſe rule for calculating the place of the harmonic, or *implied ſound*, as he calls it; *viz.* "when two different ſounds are heard together, their combination always either really produces, or eſſentially implies, a third ſound, *whoſe vibrations are equal to the difference of the vibrations of the two ſounds* in the ſame time." Thus C 240, heard together with G 360, produces 120; which is *c* an octave below C, &c. Now it is obſervable, that this empirical rule will give the ſame reſults as ours above, only in ſuch caſes where the leaſt terms of the ratio (in column 3) differs by *unity*; which is the caſe in eight of Tartini's examples out of the ten, but not with the VI or the 6th: which, according to Holden's rule, ſtand thus, 400 — 240 = 160, and $\frac{160}{240} = \frac{2}{3}$, or the fifth below the key, inſtead of the XIIth (as Dr. Robiſon and we have calculated it above); alſo, 384 — 240 = 144, and $\frac{144}{384} = \frac{3}{8}$, or the octave and fourth, or eleventh, below the upper note, inſtead of the XXII. It is not a little ſurpriſing that Mr. H. ſhould have overlooked theſe glaring inconſiſtencies of his rule, with Tartini's experiments, on which he profeſſes to have founded it; acknowledging, however, (p. 351.) that he is unable to diſcover any philoſophical principles on which theſe phenomena can be explained, and of courſe unacquainted with the writings of the two authors, from whence we have extracted as above. We ſhould not perhaps have thus adverted to Mr. Holden's eſſay, had it not been in other reſpects a moſt reſpectable work, and one through which theſe errors are likely to be widely diſſeminated among muſicians, and were not the fanciful ſyſtem of harmony, which he builds ſolely upon them, calculated to bewilder ſtill further the muſical ſtudent, who may happen to have but a ſlight knowledge of mathematics. Among the novelties of Mr. Holden's ſyſtem, he pretends to prove, by means of the implied ſounds, (calculated by his rule,) that the minor third, $\frac{5}{6}$, is a "ſuperſtructed third," and not the fundamental leſs third of the ſcale, which he ſays is expreſſed by the ratio $\frac{27}{32}$, (though *conceived probably*, as he ſays, p. 371, by the ratio $\frac{16}{19}$,) on which account we have introduced this comma-deficient minor third into our table, and when its harmonic is ſhewn to be ♭ *e*, *five octaves* below the upper note of the conſonance, inſtead of $284\frac{4}{9} - 240 = 44\frac{4}{9}$, and $44\frac{4}{9} \div 284\frac{4}{9} = \frac{5}{32}$, which expreſſes 2 VIII + 6th, or a minor twentieth below the upper note, as Mr. H.'s rule would have given it: whereas, had he uſed the true method of aſſigning the place of this harmonic or implied ſound, his boaſted fundamental leſs third, (beſides proving leſs agreeable to the ear *on trial*, p. 384, than $\frac{5}{6}$,) muſt have been degraded from the rank of concords, as having an implied ſound more than three octaves below the loweſt of its notes, which is one of the eſſential properties of concords, according to their new conceits.

Another reſult of theſe falſe principles in the Eſſay is, the admiſſion of the integer 7 among harmonic ratios (though to the excluſion of 5 × 7; 7^2, 7^3, &c. $2^2 \times 7$, $2^3 \times 7$, &c. page 341, and alſo of page 305, although 7, 11, 13, 19, &c. have real places in the *falſe* notes of the trumpet, horn, &c.), and the conſequent introduction of what the author calls a GRAVE *fourth* (ſee that article), in his deſcending ſcale, page 316. According to which alſo, the acute or comma-redundant major ſixth ($\frac{16}{27}$), belongs eſſentially to the ſcale, inſtead of the true concord $\frac{3}{5}$! We truſt that we ſhall have performed an acceptable piece of ſervice to the well-wiſhers to the harmonic ſcience, in pointing out the ſource of ſuch incongruous abſurdities as the above; and hope, that in a ſecond edition of this uſeful work nearly all which follows page 349 will be expunged, and conſigned to its merited oblivion.

The grave harmonics found by the rules and table above, are occaſioned by the coincidences of the vibrations of perfect conſonances, or the *beats* of Mr. Sauveur, but ſince the *beats* of Dr. Robert Smith alſo, or thoſe made by imperfect concords, when they occur oftener than 12 or 13 in a ſecond, occaſion a grave harmonic note to be perceived, and no theorems for calculating ſuch beats, except that of Dr. Smith from the fractions of a comma of temperament, and Mr. Emerſon's from the lengths of ſtrings, having to our knowledge been publiſhed, we ſhall here ſupply that defect in our article BEATS, and give theorems for calculating the beats made by imperfect or tempered concords whoſe vibrations per ſecond are given, *viz.*

Let N and M be the number of complete vibrations made in one ſecond, by the grave and acute notes reſpectively, of the tempered concord whoſe perfect ratio is $\frac{n}{m}$ (n being the leaſt term, in its loweſt number), and let *b* be the number of beats in one ſecond of time.

Then, if the temperament be *ſharp*, $b = n M - m N$, the beats required.

Or, if the temperament be *flat*, $b = m N - n M$, the beats required.

Take for example, the 3d in our table above, and we have $N = 240$, $M = 284\frac{4}{9}$, $n = 5$, and $m = 6$: and by the ſecond theorem above $6 \times 240 - 5 \times 284\frac{4}{9} = 17\frac{7}{9}$ the beats in one ſecond: which are, it will be obſerved, juſt double the vibrations in column five of the table, and therefore the grave harmonic thus occaſioned, is four octaves below the upper note of this comma deficient minor third. The above theorems for beats will be found of like eaſy application, in almoſt every inſtance of muſical calculations.

GRAVE *Intervals* is a term applied by Mr. Maxwell and ſeveral other correct writers, to ſuch conſonances as are flattened or lowered by a *major* COMMA (ſee that article) and it is uſual with them to diſtinguiſh ſuch intervals by the grave accent thus, IIˋ, IIIˋ, IVˋ, Vˋ, VIˋ, &c.; and on the contrary, to apply the acute accent to ſuch as are ſharpened or raiſed a major comma, as II′, III′, 4′, &c. and to call ſuch *acute intervals* or *comma redundant* intervals, while thoſe as much flattened are called COMMA *deficient intervals*, which ſee. Mr. Holden, a modern writer, has, however, applied this term to intervals lowered by what he calls a *bearing*, whoſe ratio is $\frac{63}{64} = 11.94709\Sigma + m$. See GRAVE *fourth*, &c.

GRAVE *fourth*, according to Mr. Holden's ſyſtem lately publiſhed, is an interval leſs than a perfect fourth, by what he calls a *bearing* (which is $\frac{63}{64} = 13.94709\Sigma + m$) having the ratio of $\frac{16}{21} = 240.05291\Sigma + 5f + 21m$ in Mr. Farey's new notation; its common logarithm is .8819006, 8792, its Euler's logarithm or decimal value of the octave is .3923175, and it contains 21.89039 major commas.

GRAVE *proper ſemitone*, is an interval in Mr. Holden's Syſtem of Muſic, whoſe ratio is $\frac{20}{21} = 43.05291\Sigma + f + 4m$; its common logarithm is .9788107,1, and Euler's logarithm .070389, and the number of major commas 3.92754 which it contains.

GRAVEDO, in *Medicine*, a Latin term, derived from *gravis*, heavy, ſignifies that ſpecies of catarrh, which is uſually called *a cold in the head*; and in which, together with a ſtuffing of the noſtrils, and blunting of the voice, there is a ſenſe of fullneſs and weight in the forehead. It is, according to Celſus, nearly ſynonymous with the *coryza* of the Greeks. See CATARRH. Celſus, de Med. lib iv. cap. 2.

GRAVEDONA, or GRAVIDONA, in *Geography*, a town of Italy, in the department of the Lario, on the lake Como: 42 miles N. of Milan.

GRAVEL, in *Agriculture,* a term frequently applied to a well known material of the ſmall ſtony kind, the ſizes of the particles of which vary from thoſe of very ſmall peas to cockles, and ſometimes larger. They are often intermixed with other matters, ſuch as ſand, clay, loam, flints, pebbles, iron ocres, &c. Hence there are *ſandy, clayey, loamy, flinty, pebbly, ocrey* or *ferruginous* gravels, &c.

GRAVEL, in *Gardening,* is a ſmall ſtony ſubſtance made uſe of for the purpoſe of conſtructing roads, walks and paths. Walks formed of this material are great ornaments to gardens and pleaſure-grounds, as well as uſeful for common walking upon.

The beſt gravel for thoſe purpoſes is that which is naturally compoſed of irregular pebbles and flints, having a moderate proportion of a yellowiſh or browniſh ſandy loam, to make it bind, and give colour. It is obtained in fields and commons, in many parts, at from one, to three or four feet under the ſurface, though not equally good in all parts, in reſpect to quality and colour, ſome having a greater or leſs proportion of pebbles, a larger or ſmaller proportion of loam, which is more or leſs ſandy or clayey: it is the colour of the loam, or oxyd of iron, principally, which conſtitutes the beauty of gravel walks; that of a deepiſh yellow or reddiſh colour being the moſt eligible, as when formed into well-laid walks and rolled, it has an exceedingly beautiful and ornamental effect. Where ſuch gravel can be procured within a moderate diſtance, and eaſy expence, it is preferable to all others in ſome parts. Gravel is of an iron-mould colour, or of a duſky brown hue, which may nevertheleſs be of a proper quality for walks where the colour is diſregarded.

Whatever colour the gravel may have, its proper quality for walks is, a due proportion of moderate, light, ſandy loam, to make it bind cloſe and firm at all ſeaſons; but not ſo redundant, or ſo clayey, as to be clammy and ſtick to the feet in wet weather, or ſo ſharp and ſandy as to become open and looſe in dry weather.

In ſome places, no other gravel is met with but ſuch as is very looſe, ſandy, or pebbly, and which has ſcarcely any binding materials amongſt it; which kind never of itſelf binds, but always remains open and looſe, being at all times diſagreeable to walk upon; this may, however, be mended by a mixture of light ſandy loam, where practicable, adding about one load to every two or three of gravel, caſting them together, and turning them over two or three times, that they may be well blended and incorporated; and this, when formed into a walk, will often bind cloſe, firm, and ſmooth at all ſeaſons of the year.

In preparing the gravel for walks, it ſhould not by any means be finely ſcreened, as is often the practice: as it is dug out of the pit, it is only neceſſary to caſt it up in a heap, or long ridge, all ſuch large rough pebbles only as roll down being cleared away; as if ſcreened from the ſtones, it partakes too much of the loam, ſo as always to ſtick to the feet at every flaſh of rain.

In purchaſing gravel for walks, it is moſtly from about two to five or ſix ſhillings or more per cart-load for three horſes; though the price differs greatly in different parts, and according to the nature of the gravel, as well as the goodneſs of its colour.

In reſpect to the diſtribution of gravel-walks in pleaſure-grounds, and gardens, for ornament or uſe, large ones are neceſſary to proceed parallel to the houſe, extending each way towards the ſide diſtricts of the garden and ornamented grounds: according to the former ſtyle of gardening, a large walk of this kind was uſually extended in a ſtraight line from the front of the habitation along the middle of the pleaſure ground, ſometimes having graſs plats continued on each ſide, and ſometimes ſpacious borders furniſhed with curious ſhrubs and flowers. But in modern deſigns theſe middle walks are rarely admitted, eſpecially in ſpacious grounds, having nothing in front beyond the parallel habitation walk, but an open rural graſs lawn, free from all interſections of walks, &c. However, a good walk cloſely parallel to the houſe is indiſpenſably neceſſary, both for ornament and convenience, and from this ſide-walks ſhould branch off, communicating with the other parts of the pleaſure or garden-grounds; one in particular to be extended in a ſerpentine manner quite round the ground, others leading in the ſame manner through the interior parts, ſo as to have dry firm walking at all times to every part of the ground or garden, without coming upon the graſs.

The dimenſions for gravel-walks muſt be regulated according to the extent of the grounds or gardens, as from five to twenty feet or more in width; but all principal walks ſhould be at leaſt eight or ten feet wide; and in large grounds or gardens leading directly from the houſe, they ſhould be ten, fifteen, or twenty feet wide at leaſt. When the houſes and gardens are very large, the main walks contiguous to the manſion are ſometimes made thirty or forty feet wide; the boundaries on each ſide being ſometimes in graſs widely extended, and ſometimes in borders for flowers and other curious plants, having either narrow verges of graſs, or edgings of dwarf box, or thrift, on the ſides of the walks.

In forming walks of this ſort, they ſhould be firſt ſtaked out to the proper width, and then the boundaries formed, each ſide of equal level, correſponding to the adjacent ground; the cavity of the walk for the reception of the gravel being afterwards made, the whole ſpace being dug out at leaſt twelve inches deep, to allow for a proper depth of gravel, both to prevent weeds coming from the ground below, and worms from caſting up the earth; as alſo to allow of a proper depth for turning the gravel occaſionally when the ſurface becomes foul; the earth dug out to form the cavity of the walk may be uſed to raiſe and form the ground on each ſide, if neceſſary, which, and the edgings, ſhould always be completed before the gravel is begun to be laid down into the cavity formed for it.

When the cavity has been thus prepared, any hard rubbiſhing materials may be laid in the bottom, ſeveral inches thick; ſuch as coarſe gravel or ballaſt, rough ſtony lime, brick, or other rubbiſh, which will greatly prevent worm-caſts, and help to drain the moiſture from the top of the walk in wet weather, and in winter preſerve a dry ſurface: the proper gravel is then to be laid ſix or eight inches thick; in laying, raiſing the middle higher than the ſides, in a gradual rounding form; which is not only neceſſary to throw off the wet, but alſo to give the walk a more ornamental appearance; the proportion to be obſerved in this is, for a walk of five or ſix feet width, an inch and a half of riſe in the middle; for one of ten or twelve feet, two and a half inches; and for one of twenty feet, from three to four or five inches; the ſame proportion being regarded in other widths. At every ten or fifteen feet, as the work advances in laying, it is proper to tread, rake, and roll the gravel down, as it always rolls more firm and ſmooth whilſt freſh ſtirred; it is alſo neceſſary, for fear of rain, eſpecially in loamy gravel; for which reaſons, more ſhould never be laid in one day than can be finiſhed off, except the rough laying. The treading ſhould be performed regularly with the feet pretty cloſe, taking ſhort ſteps; ſo as to render every part equally firm, and not to ſink in holes under the feet, in the work of raking and rolling. The raking ſhould be performed regularly lengthways of the walk; and in the finiſhing off or ſmooth raking, a wooden-headed rake without teeth is moſt eligible, or the back of any common rake ; as by any of theſe, the ſurface may be rendered more regular and even without drawing off the requiſite proportion of top pebbles, or raking them into holes or heaps ; as the art of ſmooth-raking is to leave all the proper-ſized top ſtones equally diſperſed over the ſurface. As ſoon as any part is thus laid and raked, it ſhould be well rolled both acroſs and lengthways ; and when the whole is laid, a good rolling ſhould be given the whole length, repeating it till the ſurface is rendered perfectly compact, firm, and ſmooth ; and after the firſt ſhower of rain, another good rolling ſhould be given, ſo as to make it bind like a rock. This method ſhould be practiſed with all walks made with theſe materials invariably.

The management afterwards is, occaſional weeding, ſweeping, and good rolling, once or twice a week, eſpecially in the advanced part of ſpring, and all ſummer ; and alſo occaſionally in winter, in dry open weather ; and when the ſurfaces become very foul, or over-run with ſmall weeds or moſs, as is often the caſe, they muſt be broken up in ſpring, and turned the ſurface to the bottom, and the bottom to the top, by which the weeds and moſs will not only be buried, but the walks appear as freſh as when new laid. The cuſtom of breaking up gravel-walks in the beginning of winter, and laying them up in rough ridges, to deſtroy weeds and moſs, is not eligible for general practice, or only occaſionally, where any walk is exceedingly overrun ; it is moſtly more adviſable to permit all the principal gravel-walks to remain undiſturbed, at leaſt till the ſpring, when, if it appear neceſſary, the whole may be broken up, regularly turned, and re-laid in a neat manner.

The turning of gravel is a ſort of ſlight digging, the foul ſurface being turned down, and the freſh up ; ſome have it performed regularly once a year in the ſpring, in order to preſerve the colour. In theſe caſes, the laying, raking, and rolling, are performed the ſame as in the firſt conſtructing the walks.

The rolling ſhould be performed once a week at leaſt in ſummer, and if two or three times the more beautiful the walks will appear, and it will tend greatly to deſtroy weeds and moſs ; it is moſtly a rule among gardeners to ſweep and roll every Saturday. During the ſummer, it is of much advantage to give a good rolling after rain, which affords a compact ſmooth ſurface, and preſerves the walks in good order.

Gravel, in *Geology*, is a term properly applied to thoſe ſabulous ſoils, or aſſemblages of worn and rounded ſtones, which are found ſcattered on the ſurface of the earth, in almoſt all ſituations. It is an eſſential character of gravel, that it ſhall contain rounded ſtones extraneous to the place where they are found, otherwiſe the breccia, rubble, and looſened rocks and ſtrata near the ſurface, owing to the action of air, wet, and froſts, &c. will be confounded with it, as too often has happened, in the deſcriptions of countries. The earthy and ſmaller matters found among gravels, vary in different ſituations, in all degrees from clay to ſand : and yet, if ſuch alluvial mixtures contain rounded ſtones, and fragments with evident marks of attrition on them, they ſhould, in deſcribing ſuch ſoils, all be denominated gravel, adding other words to diſtinguiſh the nature and quantity of their earthy mixtures : where rounded ſtones only are found, with little elſe among them, as on the ſea beach often, and in ſome gravel-pits, ſuch may be denominated very clean gravel ; if a ſmall admixture of ſand, loam, (a mixture of ſand and clay,) or clay, be found among the ſtones, ſuch may be denominated clean ſandy, clean loamy, or clean clayey gravel : where a conſiderable portion of the maſs is ſand, loam, or clay, ſuch ſhould be called ſandy, loamy, or clayey gravel : and laſtly, where the earths greatly predominate, the terms very ſandy, very loamy, or very clayey gravel ſhould be uſed ; or in place of theſe laſt, in extreme caſes, alluvial ſand, alluvial loam, or alluvial clay may be ſubſtituted : the laſt of which terms would apply to the horizontal earthy depoſits or meadow ſoils, by the ſides of rivers, the mud of lakes, &c. We have here made uſe of the term alluvial, in its ſtrict and proper ſenſe, as denoting matters worn, moved, diſperſed, mixed, and depoſited in water, in diſtinction from the regular or undiſturbed matters of the terreſtrial ſtrata : which, though they ſhew evident marks of having been depoſited in a fluid, the perfect homogenity of each lamina of the ſtrata, and their vaſt extenſion, without rude or accidental mixtures, ſhew that the laws which governed the two kinds of terreſtrial depoſit, were not leſs diſtinct and marked, than are the proceſſes of the precipitation of matters before mechanically mixed and ſuſpended in a fluid, and the cryſtallization of ſubſtances from menſtrua ſuper-ſaturated therewith. During the depoſition of the ſtrata, all was tranquil and quiet, except the movements of animated beings, which occupied ſucceſſively the vaſt ſubaqueous plains of ſtrata : during the formation and depoſition of the gravels, of all deſcriptions, all was violence and confuſion, and apparently ſo continued for a long period of time.

No problem is of more practical and theoretical importance in geology, than whether gravel is any where found *under* regular and undiſturbed ſtrata ? Were the deciſion of this queſtion to be referred to the opinions of writers on geology, mineralogy, &c. there would be little room to doubt, from their deſcription, that ſuch is ſometimes, nay frequently, the caſe ; but Mr. William Smith, from having devoted great part of twenty years to the accurate diſcrimination of ſtratified and alluvial matters, on the principles above ſtated, after examining vaſt numbers of the deepeſt and moſt extenſive wells, ſhafts, mines, quarries, &c. and converſing with quarrymen, miners, &c. who collectively have made an almoſt infinite number of obſervations, is decidedly of opinion, that no ſuch caſe can be pointed out in England. It is true, that ſandy, loamy, and clayey maſſes occur, with a very few rounded or broken and mixed ſtony fragments among them, ſo that the niceſt diſcriminations are neceſſary to diſtinguiſh ſuch, in ſome places, from ſtratified ſand, loam, (or natural brick-earth) or clay ; and under great thickneſs of ſuch doubtful maſſes, beds of rounded and mixed ſtones are found, ſometimes at very conſiderable depths, but in all ſuch inſtances, the doubtful character has continued from the very ſurface downward, to ſuch gravel-beds, and no where are regular ſtrata of ſtone, clay, or ſand found upon even theſe doubtful maſſes, when due caution is uſed in making and extending the obſervations. It is true alſo, that there are, in various parts of the Britiſh ſeries of ſtrata, ſiliceous, or grit-ſtone beds, and rocks, compoſed of diſtinct grains of ſilex, or cryſtallized quartz, of all ſizes, from ſuch as require a glaſs for viewing them, to others the ſize of a man's fiſt ; and in ſeveral inſtances, contrary to the more common caſe, of ſmall and ſizeable, or uniform grains, which diſtinguiſh moſt of our grit-ſtones, there are beds in which grains, as fine as poſſible, are mixed with the largeſt mentioned above, and have, in the cliffs and places where theſe coarſe ſtone-beds, or looſe blocks of them, are ſeen expoſed, ſo exactly the appearance, at firſt ſight, of gravel-rock, or indurated ſandy gravel, that it is no wonder they ſhould have been ſo generally claſſed with the gravels. Thoſe, however, who, like Mr. Smith, and the writer of this article, will be at the pains to trace the blocks of coarſe ſtone alluded to, to their natural bed, and to examine the newly cut, or broken faces of them, and their beds and accompanying ſtrata, and of comparing them with the heterogeneous mixtures and uncertain and irregular ſtratification of the real gravel-rocks, of which there are great tracts in Nottinghamſhire, Derbyſhire, Leiceſterſhire, Staffordſhire, Cheſhire, and others of the midland counties, in ſome places of immenſe thickneſs, will ſee abundant cauſe for diſtinguiſhing even the coarſeſt and moſt irregular of our grit-ſtone ſtrata, from the ſuperficial gravel-rocks above-mentioned, and, indeed, from alluvial, or water-worn mixtures of any kind. And ſuch obſervers will be ſtruck with ſurprize, that ſuch a regular and conſtant law, as ſeems to have regulated the formation of grains of ſilex, of all the ſizes mentioned, ſhould not have been obſerved and reſorted to, for explaining the formation of coarſe as well as fine grit-ſtones, and have guarded againſt our confounding them with the water-worn gravels. Accumulations of gravel are to be diſtinguiſhed into native and foreign, according as the pebbles and earth and extraneous bodies among them, can be referred to known and adjacent ſtrata, or conſiſts of ſtones and earths not elſewhere found, or but in very diſtant countries. For it will be found, that except on the ſea ſhore, where the waves continually carry away, and again throw up the ſtones, which fall from, or are waſhed out of the marine cliffs, that the gravel of no ſpot correſponds with the ſtrata on which it is lodged, and if in any ſituations in land this ſhould ſeem to be the caſe, it will probably be found, that thoſe ſtrata extend far to the eaſt or ſouth-eaſt of the place where their alluvial remains are lodged, and the circumſtances appear to be explainable, on the principle of a general moving of native alluvia from the ſouth-eaſt quarter towards the north-weſt quarter, as obſerved in the Philoſophical Magazine, vol. xxxv. p. 135. It is a remarkable fact, that all the very coarſe, and irregular grit-ſtone ſtrata, which have been noticed by the writer of this article in England, precede or occur beneath a ſeries of carboniferous ſtrata, or coal-meaſures; the loweſt being found in the firſt and third grit rocks of the great Derbyſhire denudation, and the others occur, both above and below the grey lime rock, which forms the floor and border of the great South-Wales coal-field (Phil. Tranſ. 1806), alſo the floor and edges of the foreſt of Dean coal-baſon, and the weſtern edge of the Somerſet and Glouceſter, or Bath coal-field, the northern edge of the Newcaſtle-underline, or pottery coal-field, &c. And which fact it ſeems to be that Mr. Kirwan alludes to, under the name of ſemiprotolite in ſome of the caſes mentioned pages 257, 293, 300, 307, 312, and 336, of his "Geological Eſſays:" it is plain, however, that theſe coarſe grit-ſtones, under our coals, do not indicate the near approach of the fundamental rock of granite, as Mr. Kirwan would have us believe. We cannot cloſe this article, without again adverting to the importance of accurately diſcriminating the alluvia found on different parts of every country, and of tracing their connection with the regular and continuous maſſes of ſtrata on which they reſt, and from whence they have been torn. Much information on the alluvia and ſtrata of the midland counties of England will be found in Mr. Farey's Report on Derbyſhire.

Gravel *Rock*, ſignifies a concreted or indurated maſs of ſandy **Gravel**, (ſee that article,) and is carefully to be diſtinguiſhed from the coarſe grit-ſtone ſtrata, which it often cloſely reſembles.

Gravel *Foſſils*, is a term applied to ſuch reliquia, or extraneous foſſils, as are found in a rounded or worn ſtate, or lodged among gravel, or alluvial mixtures, the ruins of abraded and worn ſtrata. See our article Coal, where the diſtinctions between this and other claſſes of extraneous foſſils are explained.

Gravel, in *Medicine*, the popular term for the diſorder occaſioned by the formation of ſmall calculous, or ſand-like concretions in the kidnies and bladder. It is the *Nephralgia arenoſa* of Sauvage; (ſee his Noſol. Method. Claſs VII. Genus XXV. ſpec. 2.) and to be diſtinguiſhed from the nephralgia *calculoſa* of the ſame noſologiſt, in which larger calculi, or *ſtones*, are formed and impacted in the kidnies, ureters, or bladder.

The ſymptoms which indicate the preſence of gravel in the kidnies, or in the paſſages from the kidnies to the bladder, called the ureters, are chiefly a ſevere pain in the loins, which is often accompanied by a ſenſe of numbneſs, extending down the thighs of the ſide affected, with a retraction of the teſticle in the male, and with a ſickneſs of the ſtomach, often amounting to vomiting. During the paſſage of the ſmall calculus through the canal of the ureter, the diſtenſion and irritation occaſioned by the calculus, eſpecially if its ſurface ſhould be rugged and uneven, excites thoſe ſymptoms in a more or leſs ſevere degree, or for a longer or ſhorter duration, according to its ſize and form; and they ſuddenly ceaſe when it has entered the bladder. Pain is again excited in the urinary organs, when the calculus either lies over the aperture, or enters the canal of the urethra, and a pain and difficulty of paſſing the urine is excited. Theſe ſymptoms, attending the tranſit of a ſmall ſtone from the kidney, or its expulſion from the bladder, conſtitute what is uſually called a fit of the gravel. The more common forms of the diſeaſe, however, conſiſt in the formation of a ſort of ſandy matter, of a red colour, which impedes the free paſſage of the urine, and occaſions conſiderable pain in the attempt, as well as an aching pain in the loins, through the ſympathy of the kidnies with the bladder. A whitiſh mucous matter is ſometimes diſcharged with the urine, under both theſe forms of the diſorder, probably from the irritation excited in the ſecreting veſſels, that open on the internal ſurface of the bladder: the paſſage of the ſmall calculi occaſionally cauſes a laceration of the ſmall blood-veſſels, and bloody urine is therefore diſcharged.

The little calculi, excited in thoſe caſes, are ſometimes of a bright red colour, and conſiſt, as well as the red ſand which paſſes with the urine, or is depoſited from it, of the uric or lithic acid in a concrete ſtate.

The gravel is a diſeaſe chiefly of advanced life. It is common in gouty habits, in which it often alternates with the paroxyſms of gout. It has been obſerved, too, that it deſcends by hereditary tranſmiſſion, like that diſeaſe; and that of the children of gouty parents ſome have been attacked with the gravel, while others have had the gout. It is a curious fact, alſo, that the concretions, called chalkſtones, which are depoſited in the joints in the gout, conſiſt of the ſame ſubſtance as theſe gravelly concretions, *viz* the uric acid. It is to be diſtinguiſhed from the rheumatic affection of the loins, called lumbago, by the ſickneſs which attends the more ſevere caſes, the numbneſs of the thigh and retraction of the teſticle, as well as by the mucous or bloody urine, the pain and difficulty of paſſing it, and the appearance of the ſandy ſediment in it.

Chemiſtry has enabled the phyſician to adminiſter great relief to the ſufferings occaſioned by gravel. The diſcovery, by chemical experiments, that the ſubſtance of theſe calculous and ſabulous concretions is an acid, and therefore capable of ſolution in or combination with alkaline ſubſtances, led to the adminiſtration of the alkalies internally, as remedies for the diſeaſe: and, although it has not been found, that the larger ſtones of the bladder are diſſolved or diminiſhed by the action of alkaline medicines, yet the ſmaller concretions appear to be prevented from forming, and great relief from the pain and irritation, under all the varieties of concretion, is produced by the uſe of them. Perry's ſolvent, Mrs. Stephens' medicines, and Chittick's Receipt for the ſtone, are all of the alkaline claſs. It is probable that theſe alkaline medicines operate principally on the fluids in the firſt paſſages, by neutralizing the acids occaſioned by indigeſtion, rather than by paſſing in the circulation, and combining with the uric acid in the kidnies or bladder. This would appear, partly from the fact, that the carbonated alkalies are equally or even more beneficial than the pure or cauſtic alkalies, in relieving the ſymptoms of ſtone or gravel; but it is principally proved by a circumſtance, recently aſcertained by the experiments of Mr. Home and Mr. Brande, that the abſorbent earths, eſpecially magneſia, are conſiderably more efficacious in relieving thoſe ſymptoms, and in diminiſhing the quantity of uric acid in the urine, than the alkalies themſelves. The magneſia is to be given in moderately large doſes, two or three times a day; and if it proves purgative to the bowels, a few drops of the tincture of opium may be added to it. (See Philoſoph. Tranſact. part i. for 1810.)

Of the alkalies, it would appear that the potaſs is, on the whole, more beneficial in theſe complaints than the ſoda: the pure or cauſtic potaſs may be given freely, beginning with doſes of fifteen or twenty drops, and gradually increaſing it, well diluted with any thin drink; and it may be continued for a conſiderable time with perfect ſafety. But the carbonate of potaſs is not leſs uſeful, and, eſpecially when diſſolved in water ſaturated with carbonic acid gas, it is more agreeable, and probably more efficacious. The efficacy of theſe acidulous alkaline waters was at firſt indeed attributed to the carbonic acid which they contain, and not to the alkali. (See a Medical Commentary on Fixed Air, by Dr Dobſon.) The ſoda water acidulated by the ſame gas operates in a ſimilar way, and is another agreeable mode of taking the medicine. Lime-water is likewiſe poſſeſſed of ſome remedial powers, but is leſs efficacious than the alkaline water.

All theſe aqueous liquors operate in ſome meaſure, perhaps, upon another principle; that of increaſing the quantity of fluids which paſs through the urinary organs, and thus of diluting the irritating uric ſalts, and conſequently diminiſhing the diſtreſs which they occaſion: and they may likewiſe operate negatively, by rendering the patient unable to drink the uſual quantity of wine or other ſtrong liquors. Other matters, which tend to increaſe the flow of urine, ſeem to relieve the ſymptoms of gravel, upon the principle of dilution; eſpecially ſmall doſes of the nitrous æther, or ſpiritus ætheris nitroſi, of the pharmacopœias.

When extreme pain is excited, either by the paſſing of a ſmall concretion along the canal of the ureter or of the urethra, opiates will afford a temporary relief to the ſufferings of the patient, and will perhaps aid in relaxing any ſpaſmodic contraction that may take place in theſe paſſages, and thus expedite the paſſage of the calculus. The ſame object may be promoted by the uſe of the warm bath, by fomentations to the loins and pubes, and by warm glyſters.

For the modes of relieving the ſymptoms, connected with the preſence of the larger calculi of the bladder, and of extracting theſe concretions by ſurgical means, ſee Stone:—ſee alſo Nephralgia and Nephritis.

GRAVELAINAS, in *Geography*, a town on the S.W. coaſt of the iſland of Negropont, on the ſcite of the ancient Eretria; 10 miles S. E. of Negropont.

GRAVELINES, a ſea-port town of France, in the department of the North, and chief place of a canton in the diſtrict of Bergues, ſituated in the Engliſh channel, at the mouth of the river Aa. Although it is not large, it is well fortified with baſtions, half-moons, and horn-work, and the adjacent country is interſected by canals, one paſſing to Dunkirk by Bourbourg, and another directly to Bergues. It was built in 1160, and ceded to France by the peace of the Pyrenées; 9 miles W.S.W. of Dunkirk. N. lat. 50° 59′. E. long. 2°.

GRAVELLANO, a town of Italy, in the department of the Gogna; 30 miles N. of Novara.

GRAVELLING, among *Farriers*, a diſorder incident to travelling horſes, occaſioned by little gravel-ſtones getting in between the hoof and the ſhoe, which, ſettling to the quick, fret and feſter the part.

It is cured by pulling off the ſhoe, drawing the place to the quick, picking out all the gravel, and poulticing the foot, rather than ſtopping it, according to the old practice, with horſe-greaſe and turpentine poured in hot.

GRAVELLY Land, a term applied to ſuch land as reſts upon a ſub-ſtratum of the gravel kind, or which is much intermixed with that ſort of material. This ſort of land is generally light and dry when under the plough, but apt to burn in the ſummer ſeaſon, when in the condition of graſs.

The manures ſhould be adapted to the particular natures of theſe lands; but where they are of the more light deſcriptions, they may be greatly improved by the uſe of marle, loamy clay, chalk, mud, and other ſimilar matters, as well as different ſorts of earthy compoſts. See Soil.

Gravelly *Soil*, a term ſignifying that ſort of ſoil, which is chiefly conſtituted of gravelly matters. See Soil.

GRAVEN, in *Geography*, a town of Norway, in the dioceſe of Bergen; 42 miles S.S.W. of Bergen.

GRAVENAU, a town of Bavaria; 20 miles N. of Paſſau. N. lat. 48° 48′. E. long. 13° 22′.

GRAVENWERT, a town of Bavaria; 15 miles N. of Amberg.

GRAVER, a ſteel inſtrument, ſerving to engrave on metals. The graver conſiſts of four ſides or faces, and the point uſually terminates in a lozenge: in ſome it is round, and in others ſquare. The round point is beſt for ſcoring lines, the ſquare for cutting broad and deep, and the lozenge for more delicate and fine ſtrokes and ſcratches. Le Boſſe recommends thoſe of a form betwixt the ſquare and lozenge. See Engraving.

The gravers ſhould be made of the beſt ſteel, which muſt be drawn out into ſmall rods with a charcoal fire. Theſe rods, after having been cut into the proper lengths for gravers, ſhould be ſoftened, by heating them in a charcoal fire, and ſuffering them to cool very ſlowly: let them next be filed into the deſired form, and brought back to a hard temper by heating them red-hot, and in this ſtate dipping their ends into ſoft ſoap. This ſhould be done in a perpendicular direction; for, if they be turned in the leaſt degree obliquely, the graver will warp and be crooked. If the temper of the graver be too hard after this treatment, and prevent the whetting it properly to an edge, it may be ſoftened, by laying its end on a large burning piece of charcoal till it begins to grow yellow, and then thruſting it into a lump of tallow, or dipping it in water; but if water be uſed, the graver muſt not be too hot. It may be known whether the graver be tempered to a proper hardneſs by touching the edge of it with a file, which, if any effect attends it, proves the temper to be too ſoft. The beſt proof of too great hardneſs is the breaking of the point in engraving; after which, if a new edge be made by whetting the graver, it will be frequently found very good without any other alteration. Handmaid to the Arts, vol. ii. p. 56.

The other end is fitted into a wooden handle.

Beſides engravers, the ſeal-cutters, lock-ſmiths, gun-ſmiths, gold-ſmiths, armourers, ſpurriers, &c. likewiſe make uſe of gravers.

GRAVEROL, Francis, in *Biography*, was born at Niſmes in 1635. He was educated for the profeſſion of the law, and practiſed, as an advocate, in the parliament of Toulouſe, and in the preſidial chamber of Niſmes, and as director and ſecretary of the academy in the latter place. He was not only well verſed in the ſtudies connected with his profeſſion, but deeply read in ſubjects of general literature, and particularly diſtinguiſhed for his knowledge of medals and inſcriptions. In religion he adhered ſtrictly to Calviniſtic principles, which impeded his advancement in life, and at length involved him in perſecution. To avoid the laſh of cruel laws he retired to Orange, but, not thinking himſelf ſafe there, he attempted to paſs into Switzerland. In his journey he was apprehended by the officers of the civil power, and thrown into priſon in the citadel of Montpellier. He was, after a long confinement, liberated, and died in the year 1694. His works conſiſt of ſeveral diſſertations on particular medals, and other monuments of antiquity. His "Obſervations on the Arrets of the Parliament of Toulouſe," in 4to. were much eſteemed. He was well known to all the learned in Europe, and was admitted a member of the Ricovrati at Padua. At his death he had in hand ſome other literary works. Moreri.

S'GRAVESAND, William James le, in *Biography*, was born at Bois-le-Duc in the year 1688. Having received the elements of learning at a common ſchool, he was ſent to Leyden to ſtudy the civil law, but he ſoon exhibited a decided taſte for philoſophical and mathematical ſtudies, which he determined to purſue in preference to the learning of the courts. He produced, when he was only eighteen years old, an excellent "Eſſay on Perſpective," which gave him a conſiderable reputation among the mathematicians of the age in which he flouriſhed. In 1707 he took his doctor's degree, quitted the univerſity, and ſettled at the Hague, where he practiſed at the bar, and cultivated an acquaintance with learned men. He joined ſome other perſons in conducting a periodical work, entitled "Le Journal Litteraire," which was continued without interruption from the year 1713 to 1722. S'Graveſand contributed to it the original diſſertations relating chiefly to geometry and phyſics. Among the diſcourſes moſt worthy of notice, and which were original pieces of his own compoſition, were the following, "Remarks on the Conſtruction of Pneumatical Engines:" and "An Eſſay on the Colliſion of Bodies," which was attacked by Dr. Clarke and other learned men, on account of its oppoſing the principles of the Newtonian philoſophy. In 1715 the States General ſent an embaſſy to England, to congratulate king George I. on his acceſſion to the throne of Great Britain. S'Graveſand was on this occaſion appointed ſecretary to the perſons compoſing this body, and during his ſtay in London, he became intimately acquainted with ſir Iſaac Newton, and was, upon the recommendation of that great man, admitted a member of the Royal Society. Upon his return to Holland, he was appointed profeſſor of mathematics and aſtronomy at the univerſity at Leyden. He immediately undertook to teach and illuſtrate the Newtonian philoſophy to the ſtudents of the univerſity, and in 1734 he had the additional profeſſorſhip of philoſophy conferred upon him. So great were his exertions in the ſeveral duties of his office, and in preparing for publication his ſeveral works on the ſciences, that he injured his conſtitution, and finally ſunk under his labours in 1742, when he was only fifty-four years of age. His principal publications were: (1) "Phyſices Elementa Mathematica, Experimentis confirmata, ſive Introductio ad Philoſophiam Newtonianam," which conſiſts of the author's lectures: (2) "Matheſeos Univerſalis Elementa," containing a ſyſtem of algebra for the uſe of ſtudents, with a commentary on Newton's Univerſal Arithmetic: (3) "Philoſophiæ Newtonianæ Inſtitutiones," which is an abridgment of his Elements of Phyſics: (4) "Introductio ad Philoſophiam, Metaphyſicam, et Logicam continens." His mathematical and philoſophical works, excepting the firſt article, were collected and publiſhed at Amſterdam, in 2 vols. 4to., with an account of the life and writings of the author. The private character of S'Graveſand was highly reſpectable and amiable: his morals were exemplary, and he was beloved for his generoſity, benevolence, and obliging manners. He was conſulted by the miniſters of the republic on all matters of finance, and he was of great ſervice to them in deciphering and detecting the ſecret correſpondence of their enemies.

GRAVESANDE, in *Geography*, a town of Holland, diſtant about four miles from the ſea, ſix miles W.S.W. of Delft.

GRAVESEND, a town in the hundred of Toltingtrough, in the county of Kent, England, conſiſts of ſeveral ſtreets, built on a declivity leading to the Thames; and is partly ſituated in the pariſh of Milton, which adjoins to that of Graveſend on the eaſt ſide. The early proſperity of this town received a conſiderable check in the reign of Richard II., when the French and Spaniards ſailed up the Thames in gallies, plundered and burned many of the houſes, and took a great number of the inhabitants priſoners. To alleviate the loſs, the king was induced to give the towns-people a legal claim to the water-paſſage to London, by a grant to the abbey of St. Mary le Grace. In the tenth of queen Elizabeth the pariſhes of Graveſend and Milton were incorporated by her letters patent: but the principal charter was granted by Charles I. in the year 1632. The chief officer, who had before this time been called the portreve, was by this charter conſtituted mayor; and in him, twelve jurats, twenty-four common councilmen, a ſeneſchall or high ſteward, and other inferior officers, the government of the town is now veſted. The liberty of holding two additional weekly markets on Wedneſdays and Saturdays, and an annual fair of four days, was alſo granted at the ſame time, together with a full confirmation of the excluſive privilege, conferred by king Richard, of conveying paſſengers and goods by water to the metropolis. In Auguſt 1727 the greater part of the town was deſtroyed by a fire, which commenced in a barn-yard adjoining to the church, and conſumed that fabric, with about 120 houſes, beſides outbuildings, ſtables, &c. The preſent church, which is dedicated to St. George, was erected on the old ſcite in the year 1732, under an act of the fourth of George II. which appropriated 5000*l.* for that purpoſe, from the duties on coals and culm, levied under the acts of the ninth and tenth of queen Anne, for building fifty new churches in or near London.

Graveſend has been greatly improved ſince the year 1764, when a new town-hall, having an area beneath where the poultry market is kept, was erected by the corporation. In 1767 a new wharf, crane, and cauſeway, were made, the expence of keeping which in repair is defrayed by ſmall tolls for cranage and wharfage. The increaſe of the trade, population, and buildings has been particularly rapid ſince the middle of the laſt century. Under the late act, the number of inhabitants was returned at 2483, and that of houſes at 412; yet theſe numbers are very incorrect, and the population can ſcarcely amount to leſs than 4000, nor the number of houſes be fewer than 700. Moſt of the inhabitants are engaged in maritime purſuits or employments. A ſmall manufactory for cables and ropes is carried on here; and about the year 1780, a yard for ſhip-building, which had long been diſuſed, was hired by a quaker, named Cleverly, and ſeveral men of war and frigates, beſides ſmaller veſſels, have been built here. About eighteen or twenty ſmacks find employment in the cod and haddock fiſhery; and moſt of the Dutch turbot veſſels lie off this town, and ſend their cargoes to the London markets in ſmall boats. Moſt of the Eaſt and Weſt India trade, and, indeed, of the outward-bound ſhips in general, are ſupplied with live and dead ſtock at Graveſend; and alſo with vegetables; about eighty acres of ground in the two pariſhes being cultivated for that purpoſe, and for ſupplying the London markets with aſparagus, which is remarkable for its ſize and fine flavour. Graveſend is ſituated 22 miles E. from London. Haſted's Hiſtory of Kent, vol. i. 8vo. Beauties of England and Wales, vol. vii.

GRAVESEND, a townſhip and village of America, in Long iſland, New York, ſeven miles from the city, containing 489 inhabitants.

GRAVIMETER. See HYDROMETER.

GRAVINA, DOMENICO DA, in *Biography*, who flouriſhed in the fourteenth century, was a native of Gravina, in the kingdom of Naples. He was by profeſſion a notary, but in literature an hiſtorian. He ſeems to have taken an active part in the civil wars which agitated his country at that period, and on account of the ſide which he eſpouſed, he was ſtripped of all his property, and driven into exile with his wife and children. He wrote a hiſtory of Naples in the Latin language, and likewiſe a hiſtory of the tranſactions in that part of Italy during his own times, from 1330 to 1350. A fragment of this work only is in exiſtence, the beginning and end being loſt; it is, however, reckoned a valuable document for the fidelity of the narration, and is to be found in Muratori's collection of Italian hiſtorians.

GRAVINA, JOHN VINCENT, was born in 1664 at Rogiana, a caſtle in Calabria. He enjoyed all the advantages of a very liberal education, and became well verſed in the learned languages; geometry, phyſics, hiſtory, and antiquities. He alſo made himſelf acquainted with the principles of theology. Having thus attained to a general knowledge of the learning of the times, he went to Naples to ſtudy the civil and canon law. After this he paſſed to Rome, and lived with Paul Coardo of Turin. He was one of the original founders of the academy of Arcadi, and had the charge of drawing up their laws in the ſtyle of the Roman tables. He arrogated to himſelf the merit of having deviſed theſe laws, a circumſtance which involved him in a quarrel with the other members, particularly with Creſcimbeni, the founder of the ſociety, ſo that theſe two learned men were for ſeveral years at the head of two factions which divided the [illegible]. In 1698, he was nominated profeſſor of civil law at the college of Sapienza, and, in two years after, he ſucceeded to the chair of the canon-law. His method of inſtruction was excellent; he avoided trifling verbal diſputes, and vain ſcholaſtic ſpeculations, and entered into the ſpirit of the laws, illuſtrating their theory by obſervations drawn from ancient writers, and by a criticiſm founded on his extenſive erudition. This mode of inſtruction excited much public attention, but the haughtineſs of his temper prevented him from being popular. By the public at large, his manners could be no obſtacle to the celebrity of his writings, and his reputation daily increaſed. His works were numerous, and the ſubjects on which he treated very various. His "Origines Juris Civilis," has been ever eſteemed a claſſical performance, lucid in its arrangements, and replete with ſolid and very important learning. This was firſt publiſhed at Leipſic in 1708, and afterwards there was a more correct edition of it in 1713; to the latter impreſſion was ſubjoined a treatiſe "De imperio Romano," eſteemed a maſter-piece, though not free from error. Gravina undertook to eſtabliſh a poetical code, for which purpoſe he wrote two books, entitled "Della Region Poetica:" one entitled "Della Tragedia," and a treatiſe "De Inſtitutione Poetarum." Another work was printed contrary to his inclination; this was his "Inſtitutes of Civil and Canon Law," which he intended to have reviſed and given in a corrected and augmented form. In 1714, Gravina re-viſited his native country, where he ſtaid about two years and then returned to Rome. He was preparing to depart for Turin, whither he had been invited by the duke of Savoy, in order that he might take the general direction of the learned inſtitutions, when he was ſeized with an illneſs which carried him off in 1718, in the arms of his beloved pupil Metaſtaſio, whoſe poetical talents he firſt diſcovered and cheriſhed, and whom he left heir of all his property out of Calabria. Gravina was of a contentious diſpoſition, exceſſive in his praiſe of perſons whom he eſteemed, and alſo in his cenſure of thoſe who offended him; he was arrogant, from a high opinion of his own ſuperiority. This created him many enemies, with whom he was perpetually at war. Of his great learning there can be no doubt; but with reſpect to his poetical talents, it has been remarked, that he was more ſucceſsful as a legiſlator than as a practiſer in the art; for his five tragedies written on the model of the ancients were not favourably received by the public, and the author's angry expoſtulation, proving that they ought to have been applauded as uſual, was totally inefficacious. Moreri.

GRAVINA, in *Geography*, a town of Naples, in the province of Bari, the ſee of a biſhop, ſuffragan of Acerenza, 24 miles S. of Trani.

GRAVINA'S *Iſlands*, a range of iſlands in the N. Pacific ocean, each from 20 to 50 miles in circumference, interſperſed with ſome iſlets, ſtretching N. W. to S. E. about 40 miles, between the duke of Clarence's ſtrait and the canal of Revilla Gigedo. N. lat. 54° 52′ to 55° 27′. E. long. 228° 24′ to 229° 5′.

GRAVING, the act or art of cutting lines, figures, and other deſigns, on metals; more properly called *engraving;* which ſee.

GRAVING, in the *Sea Language*, is the bringing a ſhip a-ground, and then burning off with furze, reed, or broom, all the filth and foulneſs that ſtick to her bottom without board, in order to pay her anew. See BROOMING and CAREENING.

GRAVING-*dock*, or *Dry Dock*, is a place from which the water can be let out or pumped, after ſhips and boats are floated into it to be cleaned or repaired; ſometimes, graving-docks are above the level of the water, and boats are dragged upon inclined planes into the ſame. By the ſides of tidal rivers or harbours there are conſtructed with ſtrong cloſe gates meeting in an angle to ſhut out the tide; which gates are furniſhed with a ſmall ſluice or valve for emptying or filling the dock, when a veſſel has entered at high water, or is about to leave the dock at ſuch time. See Docks, and Canal.

GRAVISKOI, in *Geography*, a fortreſs of Ruſſia, in the government of Kolivan, on the Irtiſch; 240 miles S. S. W. of Kolivan. N. lat. 50° 15′. E. long. 75° 14′.

GRAVITAS, Βαρυτης, in the *Ancient Muſic*, was uſed to ſignify a ſound produced by the remiſſion or falling of the voice. Gravitas differs from remiſſion, as the effect from the cauſe.

Gravitas is alſo uſed to denote the ſtate of a woman going with child. See Pregnancy.

GRAVITATION, the exerciſe of gravity, or the action which a body exerts on another body by the power of gravity. It is ſometimes diſtinguiſhed from gravity. Thus, Maupertuis takes gravity for that force by which a body would fall to the earth ſuppoſed at reſt; and gravitation for the ſame but diminiſhed by the centrifugal force. See figure of the earth determ. p. 206 of Mr. Murdoch's tranſlation.

It is only gravitation, or gravity thus blended with the centrifugal force, that we can meaſure by our experiments. However, methods have been found to diſtinguiſh what remains of primitive gravity, and what has been deſtroyed by the centrifugal force.

It is one of the laws of nature, diſcovered by ſir Iſaac Newton, and now received by moſt philoſophers, that every particle of matter in nature gravitates towards every other particle; which law is the hinge on which the whole Newtonian philoſophy turns. See Newtonian *Philoſophy*.

What we call *gravitation*, with reſpect to the gravitating body, is properly called *attraction* with reſpect to the body towards which the other gravitates.

The planets, both primary and ſecondary, and alſo the comets, do all gravitate towards the ſun, and towards each other; and the ſun towards them: and that in proportion to the quantity of matter in each.

The Peripatetics, &c. hold, that bodies only gravitate when out of their natural places, and that gravitation ceaſes when they are reſtored to the ſame, the intention of nature being then fulfilled. The final cauſe of this faculty, as they maintain, is only to bring elementary bodies to their proper place, where they may reſt. But the moderns ſhew, that bodies exerciſe gravity even when at reſt and in their proper places.

This is particularly ſhewn of fluids; and it is one of the laws of hydroſtatics demonſtrated by Mr. Boyle and others, that fluids gravitate *in proprio loco*, the upper parts preſſing on the lower, &c.

For the laws of gravitation of bodies in fluids ſpecifically lighter, or heavier than themſelves, ſee *Specific* Gravity, Fluid, &c.

Gravitation, *Theory of Univerſal*. Newton is very juſtly conſidered as the author of this great hypotheſis, though ſeveral preceding and cotemporary writers ſeem to have formed conjectures on this ſubject that did not differ very widely from the truth. From the time of Kepler it had every day become more and more evident, that ſome mechanical cauſe had a very material influence on the laws of the planetary motions. The problems which the diſcoveries of that great aſtronomer had left for future ages to ſolve were theſe: Why do the planets and ſatellites deſcribe *elliptic* orbits, the former round the ſun, the latter round their primary planet? Why is the centre of motion in the focus rather than in the centre of the ellipſe? Why are equal areas deſcribed in equal times about the centre; and what can be the cauſe of that remarkable law that is found conſtantly to ſubſiſt between the diſtances of the planets from the ſun and the times of their revolution?

Des Cartes firſt attempted a ſolution of theſe difficulties, by ſuggeſting a ſimple mechanical cauſe. He ſuppoſed the exiſtence of a ſubtile fluid, which, though imperceptible to the ſenſes, was in conſtant motion round the ſun, and that it involved the planets in its powerful agency. This theory, on its firſt enunciation, does not ſeem deficient in plauſibility, but upon more careful examination, it is found incapable of explaining any one aſtronomical phenomenon correctly, and indeed the action of ſuch a fluid would produce effects in many caſes exactly the reverſe of what it was intended to explain. The ſpirit of rational enquiry that now began to be exerted on all philoſophical ſubjects, rendered this theory of ſhort duration.

Kepler at a much earlier period had formed more correct opinions on this ſubject than Des Cartes: indeed he ſeems to have had a very diſtinct idea of the exiſtence of gravitation, though he never could have been aware of its agency being ſo extenſive, or that it would ever explain in ſo ſatisfactory a manner as it has done his own great diſcoveries. Gravity, he ſays, in his "Commentary on Mars," is only a mutual and corporeal affection between ſimilar bodies. Heavy bodies do not tend to the centre of the world, but to that of the round body of which they form a part; and if the earth were not ſpherical, heavy bodies would not fall towards its centre, but towards different points. This conjecture has been fully verified by theory and obſervation; the earth appears not to be a perfect ſphere, and accordingly a plumb-line does not tend to the exact centre of gravity of the whole earth, but to a point conſiderably remote from it, as has been explained under Degree, Earth, *figure of*, &c. &c.

Kepler likewiſe ſtrongly ſuſpected that the attraction of the moon was the cauſe of the tides, and that the lunar irregularities aroſe from the action of the earth and ſun. Perhaps, from the earlieſt times, ſome indiſtinct conceptions are to be occaſionally traced in different authors concerning the exiſtence of this univerſal principle.

Fermat, who preceded Kepler, affirmed, that the weight of a body was the ſum of the tendencies of all its particles to all the particles of the earth; and Kepler was of opinion that two bodies left alone in free ſpace would approach each other with velocities inverſely proportional to their maſſes or quantities of matter.

A ſhort time previous to the great diſcovery of Newton, Dr. Hooke made a ſtill nearer approach to the truth. At a meeting of the Royal Society, May 3, 1668, he expreſſed himſelf in the following manner: "I will explain a ſyſtem of the world very different from any yet received, and it is founded on the three following poſitions:

1. That all the heavenly bodies have not only a gravitation of their parts to their own proper centres, but that they alſo mutually attract each other within their ſpheres of action.

2. That all bodies having a ſimple motion will continue to move in a ſtraight line, unleſs continually deflected from it by ſome extraneous force, cauſing them to deſcribe a circle, an ellipſe, or ſome other curve.

3. That this attraction is ſo much the greater as the bodies are nearer. As to the proportion in which thoſe forces diminiſh by an increaſe of diſtance, I own I have not yet diſcovered it, although I have made ſome experiments to this purpoſe. I leave this to others who have time and knowledge ſufficient for the taſk."

This is a very preciſe enunciation of a proper philoſophical theory. The phenomenon, the change of motion, is conſidered as the mark and meaſure of a change of force, and his audience is referred to experience for the nature of this force. He had before exhibited to the ſociety a very pretty experiment contrived to ſhew the nature of this force. A ball, ſuſpended by a long thread from the ceiling, was made to ſwing round another ball, laid on a table immediately below the point of ſuſpenſion. When the impulſe given to the pendulum was nicely adjuſted to its deviation from the perpendicular, it deſcribed a perfect circle round the ball on the table; but when the impulſe was very great, or very ſmall, it deſcribed an ellipſe, having the other ball in its centre.

Hooke ſhewed that this was the operation of a deflecting force proportioned to the diſtance from the other ball. He added, that although this illuſtrated the planetary motions in ſome degree, yet it was not ſuitable to their caſe: for the planets deſcribe ellipſes, having the ſun not in their centre but in their focus. Therefore they are not retained by a force proportional to the diſtance from the ſun.

The exalted genius of Newton can ſuffer no diminution by the enumeration of the above opinions, for though the idea of ſuch a principle as gravitation was not ſuggeſted firſt by Newton, yet ſo very obſcure were the notions of even the moſt enlightened philoſophers on this ſubject, that it had never been ſucceſsfully applied to the explanation of a ſingle aſtronomical phenomenon.

So intimately connected is this great diſcovery with the hiſtory of the human mind, that every known circumſtance relating to it has been recorded with the greateſt care. Dr. Pemberton relates that Newton, in the year 1666, having retired from Cambridge to the country on account of the plague, was there led to meditate on the probable cauſe of the planetary motions, and upon the nature of that central force that retained them in their orbits. It then occurred to him that poſſibly the ſame force, or ſome modification of the ſame force which cauſed with us a heavy body to deſcend with a certain velocity to the earth, might likewiſe retain the moon in her orbit by cauſing a conſtant deflection from a rectilinear path. Before, however, this conjecture could be put to the teſt of calculation, it was neceſſary that Newton ſhould have formed ſome conditional hypotheſis relative to the modification of the force with reſpect to the diſtance. That any agency emanating from a central point ſhould decreaſe as the ſquare of the diſtance from that point increaſes, is an hypotheſis ſo natural, that we cannot be ſurprized that Newton ſhould have ſelected it; but whether or not he had previouſly tried any other, or whether he had even at this time deduced it from the nature of the planetary orbits, does not now appear. The calculation which it was neceſſary to inſtitute, we ſhall give with great minuteneſs in its proper place; it is therefore only neceſſary to remark at preſent, that it requires that the proportion between the radius of the earth and the lunar orbit ſhould be exactly known. When Newton firſt attempted to verify this hypotheſis, theſe requiſite data had not been exactly determined, and a ſlight diſcordance between the reſult of the calculation and the ſuppoſed fact, induced him for a time to abandon his hypotheſis. This circumſtance has, with great propriety, been recorded as a ſtriking inſtance of the cool and diſpaſſionate frame of mind which this great philoſopher preſerved, at a moment when he had flattered himſelf with the hope of having diſcovered one of the moſt important ſecrets of nature.

Some few years afterwards he was again tempted to renew theſe calculations, as in this interval a degree of the meridian had been meaſured in France by Picard. This ſecond attempt ſucceeded. It is related, that towards the end of the calculation he became ſo much agitated, as to be obliged to requeſt a friend to aſſiſt him in finiſhing it; and certainly a moment of greater importance in philoſophy will never be recorded in the annals of ſcience.

The computation which was made by Newton to determine the identity of the force of terreſtrial gravity, with that which retains the moon in her orbit, is ſtill a ſubject of great intereſt to aſtronomers, as they now reverſe the proceſs; and taking the theory of gravitation as admitted, they deduce from the ſame computation the diſtance of the moon from the earth. We ſhall give it in the words of La Place.

The force which at every inſtant deflects the moon from the tangent of her orbit, cauſes it to deſcribe, in one ſecond, a ſpace equal to the verſed ſine of the arc which it deſcribes in that time; ſince this ſine is the quantity that the moon at the end of a ſecond deviates from the direction it had at the beginning. This quantity may be determined by the diſtance of the earth, inferred from the lunar parallax in parts of the terreſtrial radius; but to obtain a reſult independent of the inequalities of the moon, we muſt take for the mean parallax that part of it which is independent of theſe inequalities. This part is, according to obſervation, 50′ 54″.9, relatively to the radius drawn from the centre of gravity of the earth, to the parallel, of which the ſquare of the ſine of the latitude is equal to $\frac{1}{3}$. We ſelect this parallel becauſe the attraction of the earth, on the points correſponding to its ſurface, is at the diſtance of the moon, very nearly equal to the maſs of the earth divided by the ſquare of the diſtance from its centre of gravity. The radius drawn from a point of this parallel to the centre of gravity of the earth is 6369374 metres, from whence it may be computed the force which ſolicits the moon towards the earth cauſes it to fall 0′00101727 in one ſecond of time. It will be ſhewn hereafter, that the action of the ſun diminiſhes the lunar gravity $\frac{1}{358}$th part. The preceding height muſt therefore be augmented $\frac{1}{358}$th part, to render it independent of the action of the ſun; it then becomes 0^{me}.00102011. But in its relative motion round the earth, the moon is ſolicited by a force equal to the maſſes of the earth and moon divided by the ſquare of their mutual diſtance; therefore to obtain the height which the moon would fall through in one ſecond, by the action of the earth alone, the preceding ſpace muſt be diminiſhed in the ratio of the maſs of the earth to the ſun, and of the maſſes of the earth and moon: but by the phenomena of the tides, it appears that the maſs of the moon is equal to $\frac{1}{58.7}$ of that of the earth, multiplying therefore this ſpace by $\frac{58.7}{59.7}$, we have 6^{me}.00100300 for the height which the moon falls through in one ſecond by the action of the earth.

Let us now compare this height with that which reſults from obſervations made on the pendulum. Under the parallel above-mentioned the length of the pendulum vibrating ſeconds is equal to 3^{me}.65706: but on this parallel the attraction of the earth is leſs than the force of gravity by $\frac{2}{3}$ of the centrifugal force due to the motion or rotation of the earth at the equator; and this force is $\frac{1}{289}$th part of that of gravity; the preceding ſpace muſt therefore be augmented $\frac{1}{432}$d part, to get the ſpace due to the action of terreſtrial gravity alone, which on this parallel is equal to the maſs divided by the ſquare of the terreſtrial radius: we ſhall therefore have 3^{me}.66553 for this ſpace. At the diſtance of the moon it ſhould be diminiſhed in the ratio of the ſquare of the radius of the terreſtrial ſpheroid to the ſquare of the diſtance of the moon: for this purpoſe it is ſufficient to multiply it by the ſquare of the tangent of the lunar parallax, or 56′ 55″.2, this will give 0^{me}.00100483 for the height which the moon ſhould fall through in one ſecond by the attraction of the earth. This quantity, derived from experiments on the pendulum, differs very little from that which reſults from direct obſervation of the lunar parallax; to make them coincide, it is ſufficient to diminiſh the parallax 2″, and to reduce it to 56′ 53″.3. This is the parallax reſulting from the theory of gravity, differing only $\frac{1}{1600}$dth part from that derived from actual obſervation, to which La Place thinks it preferable, conſidering the exactneſs of the elements from which it is computed. It would be ſufficient to diminiſh a little the maſs of the moon to obtain, by this theory of gravity, the ſame parallax that is given by obſervation: but all the phenomena of the tides concur in giving this ſatellite a maſs more conſiderable, and very nearly ſuch as has been uſed in the above computation. But however that may be, the ſmall difference between the two parallaxes is within the limits of the errors of obſervation, and of the elements employed in the calculation. It is then certain that the force which retains the moon in its orbit, is the terreſtrial gravity diminiſhed in proportion to the ſquare of the diſtance.

Having thus ſhewn how the nature of the force which retains the moon in its orbit is inveſtigated, it next remains to inquire if the ſame force of gravity pervades the reſt of the ſolar ſyſtem. The ſame great mathematician, above quoted, obſerves, that "of all the phenomena of the ſolar ſyſtem, the elliptic motion of the planets, and of the comets, ſeems the moſt proper to conduct us to the general law of the forces by which they are animated.

Obſervation has ſhewn, that the areas deſcribed by the radii vectores of the planets and comets about the ſun are proportional to the times. Now we ſee, in the article Central *Forces*, that, for this to take place, the force which deflects the path of theſe bodies from a right line muſt conſtantly be directed towards the origin of their radii vectores. The tendency of the planets and comets to the ſun is therefore a neceſſary conſequence of the proportionality of theſe areas to the times in which they are deſcribed. To determine the law of this tendency, let us ſuppoſe that the planets move in circular orbits, which ſuppoſition does not greatly differ from the truth. The ſquares of their real velocities will then be proportional to the ſquares of the radii of theſe orbits, divided by the ſquares of the times of their revolutions. But, by the law of Kepler, the ſquares of theſe times are to each other as the cubes of their radii; the ſquares of the velocities are therefore as theſe radii. It has been ſhewn, that the central forces of bodies, moving in circular orbits, are as the ſquares of the velocities, divided by the radii of the circumferences deſcribed; the tendency, therefore, of the planets to the ſun, is reciprocally as the ſquares of the radii of their orbits, ſuppoſed circular. This hypotheſis, it is true, is not rigorouſly exact; but the conſtant relation of the ſquares of the times to the cubes of the greater axes of their orbits being independent of their excentricities, it is natural to think it would ſubſiſt alſo in the caſe of the orbits being circular. Thus, the law of gravity towards the ſun, varying reciprocally as the ſquare of the diſtance, is clearly indicated by this relation: analogy would lead us to ſuppoſe that this law, which extends from one planet to another, ſhould ſubſiſt equally for the ſame planet at its different diſtances from the ſun; and its elliptic motion confirms this beyond a doubt. To comprehend this, let us attend to this motion, beginning at the departure from its perihelion. Its velocity is then at its maximum, and its tendency to recede from the ſun ſurpaſſing its gravity towards it, its radius vector augments, and forms an obtuſe angle with the direction of its motion. The force of gravity towards the ſun, decompoſed according to this direction, continually diminiſhes the velocity till it arrives at the aphelion; at this point the radius vector becoming perpendicular to the curve, its velocity is a minimum; and its tendency to recede from the ſun being leſs than its gravity towards it, the planet will approach it while deſcribing the ſecond part of its ellipſe. In this part, the gravity towards the ſun increaſes its velocity in the ſame manner as it before decreaſed it; and the planet will arrive at its perihelion with its primitive velocity, and recommences a new revolution, ſimilar to the firſt. Now the curvature of the ellipſe at the aphelion and perihelion being the ſame, the radii of curvature are the ſame, and, conſequently, the centrifugal forces of theſe two points are as the ſquares of the velocities. The ſectors deſcribed in the ſame time being equal, the aphelion and perihelion velocities are reciprocally as the correſponding diſtances of the planet from the ſun; the ſquares of theſe velocities are therefore reciprocally as the ſquares of theſe diſtances; but at the perihelion and aphelion diſtances, the centrifugal forces in the oſculatory circumferences are evidently equal to the gravity of the planet towards the ſun, which is therefore in the inverſe proportion to the ſquares of theſe diſtances. Thus the theorems of Huygens on the centrifugal force were ſufficient to demonſtrate the tendency of the planets towards the ſun: for it is highly probable that this law, which extends from one planet to another, and which is verified in the ſame planet, at its aphelion and perihelion, extends alſo to every part of the planetary orbit, and at the ſame time to every diſtance from the ſun. But to eſtabliſh it in an inconteſtible manner, it was requiſite to determine the general expreſſion of the force which, directed towards the focus of an ellipſe, would oblige the projectile to deſcribe that curve. And it was Newton who demonſtrated that this force was reciprocally as the ſquare of the radius vector. It was eſſential alſo to demonſtrate rigorouſly that the force of gravity towards the ſun only varies in one planet from the ſame force in another, according to their different diſtances from it.

This great geometrician ſhewed, that this followed neceſſarily from the law of the ſquares of the periodic times being reciprocally as the cubes of the diſtances; ſuppoſing therefore all the planets at reſt at the ſame diſtance from the ſun, and abandoned to their gravity towards its centre, they would deſcend from the ſame height in equal times: this reſult ſhould alſo extend to the comets, notwithſtanding the greater axes of their orbits are unknown; for we have ſeen in the ſecond book, that the magnitude of the areas deſcribed by their radii vectores, ſuppoſes the law of the ſquares of the periodic times proportional to the cubes of their axes.

A general analyſis, which embraces every poſſible reſult from a given law, ſhews us that not only an ellipſe, but any other conic ſection, may be deſcribed by virtue of the force which retains the planets in their orbits; a comet may therefore move in an hyperbola, but then it would be only once viſible, and after its apparition would recede from the limits of the ſolar ſyſtem, to approach other ſuns, which it would again abandon, thus viſiting the different ſyſtems that are ſcattered in the immenſity of the heavens. It is probable, conſidering the infinite variety of nature, that ſuch bodies exiſt. Their apparition ſhould be a very rare occurrence; the comets, we uſually obſerve, are thoſe which, having cloſed orbits, return, at the end of intervals more or leſs conſiderable, into the regions of ſpace that are in the vicinity of the ſun. The ſatellites tend alſo perpetually to the ſun. If the moon was not ſubject to its action, inſtead of deſcribing an orbit almoſt circular round the earth, it would ſoon abandon it; and if this ſatellite, and thoſe of Jupiter, were not ſolicited towards the ſun, according to the ſame law as the planets, perceptible inequalities would reſult in their motions which have not been recognized by obſervation.

The planets, comets, and ſatellites are therefore ſubject to the ſame law of gravity towards the ſun. At the ſame time that the ſatellites move round their planet, the whole ſyſtem of the planet and its ſatellites is carried by a common motion, and retained by the ſame force, round the ſun. Thus the relative motion of the planet and its ſatellites is nearly the ſame as if the planet was at reſt, and not acted upon by any external force.

We are thus conducted, without the aid of hypotheſis, by a neceſſary conſequence of the laws of the celeſtial motions, to conſider the ſun as the centre of a force, which, extending infinitely into ſpace, diminiſhes as the ſquare of the diſtance increaſes, and which attracts all bodies that are within the ſphere of its activity. Every one of the laws of Kepler diſcovers a property of this attractive force. The law of the proportionality of the areas to the times ſhews us, that it is conſtantly directed towards the centre of the ſun. The elliptic orbits of the planets ſhew that this force diminiſhes as the diſtance increaſes; finally, the law of the proportionality of the ſquares of the periodic times to the cubes of the diſtances demonſtrates, that the gravity of all the planets towards the ſun is the ſame at equal diſtances. This gravity may be called the ſolar attraction when it is conſidered as relative to the centre of the ſun, towards which it is directed; for without knowing the cauſe, we may by one of thoſe ſuppoſitions, common among geometricians, imagine an attractive power reſiding in the centre of the ſun.

The errors to which obſervations are liable, and the ſmall alterations in the elliptic motions of the planets, leave a little uncertainty in the reſults deduced from the laws of motion; and it may be doubted if the ſolar attraction diminiſhes exactly in the inverſe ratio of the ſquare of the diſtance. But a very ſmall variation in this law would produce a very perceptible difference in the motions of the planetary orbits. The perihelion of the terreſtrial orbit would have an annual motion of 1° 5′ if we only increaſed by one ten thouſandth part the power of the diſtance to which the ſolar orbit is reciprocally proportional; this motion is only 11″.6 according to obſervation, and of this we ſhall hereafter ſee the cauſe. The law of the ſquare of the diſtance is then, at leaſt, extremely near, and its extreme ſimplicity ſhould induce us to adopt it, as long as obſervations do not compel us to abandon it. At the ſame time we muſt not meaſure the ſimplicity of the laws of nature by our facility of conception, but when thoſe which appear to us the moſt ſimple accord perfectly with obſervations of the phenomena, we are juſtified in ſuppoſing them rigorouſly exact.

The gravity of the ſatellites towards the centre of their planet, is the neceſſary conſequence of the proportionality of the areas deſcribed by their radii vectores to the times, and the law of the diminution of this force, according to the ſquare of the diſtance, is indicated by the ellipticity of their orbits. But this ellipticity is hardly to be perceived in the orbits of the ſatellites of Jupiter, Saturn, and Uranus, which renders the law of the diminution of the force difficult to aſcertain by the motion of any one ſingle ſatellite; but the conſtant ratio of the ſquares of the times of their revolutions to the cubes of their diſtances, indicates it beyond a doubt, by demonſtrating, that from one ſatellite to another, the gravity towards the planet is reciprocally as the ſquare of the diſtance from its centre.

This proof is wanting for the earth, it having but one ſatellite, but it may be ſupplied from the following conſiderations:

The force of gravity extends to the ſummits of the higheſt mountains, and the ſmall diminution which it there experiences, leaves no doubt but that this force would be perceptible at much greater altitudes. Is it not natural to extend this to the moon, and to ſuppoſe that the force which retains it in its orbit, is its gravity towards the earth, in the ſame manner as the ſolar gravity retains the planets in their orbits round the ſun? for, in fact, theſe two forces ſeem to be of the ſame nature; they both of them penetrate the moſt intimate parts of matter, animating them with the ſame velocities; for we have ſeen that the ſolar gravity ſolicits equally all bodies placed at equal diſtances from the ſun, and that the terreſtrial gravity alſo cauſes all bodies to fall through the ſame height in equal times.

A heavy body, projected with force horizontally from a great height, falls on the earth at a conſiderable diſtance, deſcribing a curve, which is apparently parabolic; it will fall ſtill further, if the force is greater, and ſuppoſing it about ſeven thouſand metres in a ſecond, it would not fall to the earth, but would circulate round it like a ſatellite, ſetting aſide the reſiſtance of the air: for it has been fully ſhewn above, that, to form a moon of this projectile, it muſt be taken to the height of that body, and there receive the ſame motion of projection; and the identity of the moon's tendency to the earth, has been already demonſtrated, by ſhewing that to obtain this tendency, it is ſufficient to diminiſh the terreſtrial gravity according to the general law of the variation of the attractive force of the celeſtial bodies: and we have ſeen, that the law of the diminution of gravity, which in planets, accompanied by ſeveral ſatellites, is proved by a compariſon of their periodic times, with their diſtances, is demonſtrated for the moon, by comparing its motion with that of projectiles, at the ſurface of the earth.

The obſervations of the pendulum made at the ſummits of mountains, had already indicated this diminution of the terreſtrial gravity; but they were inſufficient to diſcover the law, becauſe of the ſmall height of the moſt elevated mountains, compared with the radius of the earth: it was requiſite to find a body very remote from us, as the moon, to render the law perceptible, and to convince us, that the force of gravity on the earth is only a particular caſe of a law that pervades the whole univerſe.

Every phenomenon throws new light on, and confirms the laws of nature. Thus the compariſon of experiments on gravity with the lunar motion ſhews us, that the origin of the diſtances of the ſun and planets, in the calculation of their attractive forces, ſhould be placed in their centres of gravity; for it is evident, that this takes place on the earth, whoſe attractive force is of the ſame nature as that of the ſun and planets.

The ſun, and thoſe planets which are accompanied by ſatellites, being thus proved to be endowed with an attractive force, varying inverſely as the ſquare of the diſtance, a ſtrong analogy leads us to attribute the ſame property to the other planets. The ſpherical figure common to all theſe bodies, indicates that their particles are united round their centres of gravity by a force which, at equal diſtances, equally ſolicits them towards theſe points; but the following conſiderations leave no doubt upon this ſubject.

We have ſeen, that if the planets and comets were placed at the ſame diſtance from the ſun, their gravity towards it would be in proportion to their maſſes: now, it is a general law in nature, that action and re-action are equal and contrary; all theſe bodies, therefore, re-act on the ſun, and attract in proportion to their maſſes; they are therefore endowed

dowed with an attractive force proportional to their maſſes, and varying inverſely as the ſquare of the diſtance. By the ſame principle, the ſatellites attract the planets and the ſun according to the ſame law. This attractive property, then, is common to all the celeſtial bodies: it does not diſturb the elliptic motion round the ſun, when we conſider only their mutual action; for the relative motion of the bodies of a ſyſtem are not changed by giving them a common velocity: by impreſſing, therefore, in a contrary direction to the ſun and to the planet, the motion of the firſt of theſe two bodies, and the action which it experiences on the part of the ſecond, the ſun may be conſidered as immoveable, but the planet will be ſolicited towards it with a force varying reciprocally as the ſquare of the diſtance, and proportional to the ſum of the maſſes; its motion round the ſun will therefore be elliptic. And we ſee by the ſame reaſoning, that it would be ſo if the planet and ſun were carried through ſpace with a motion common to each of them. It is equally evident that the elliptic motion of a ſatellite is not diſturbed by the motion of tranſlation of its planet, nor would it be by the action of the ſun, if it was always exactly the ſame on the ſatellite and the planet.

Nevertheleſs, the action of the planet on the ſun influences the length of its revolution, which is diminiſhed as the maſs of the planet is more conſiderable; ſo that the relation of the ſquare of its periodic time, to the cube of the major axis of its orbit, depends on its maſs. But ſince this relation is nearly the ſame for all the planets, their maſſes muſt evidently be very ſmall compared with that of the ſun, which is equally free for the ſatellites with reſpect to their principal planets.

This we may readily ſuppoſe from their ſmallneſs.

The attractive property of the heavenly bodies not only belongs to them in a maſs, but to each of their particles. If the ſun only acted on the centre of the earth without attracting particularly every one of its particles, oſcillations would ariſe in the ocean, infinitely more conſiderable and very different from thoſe which we obſerve. The gravity of the earth to the ſun, therefore, is the reſult of the gravity of all its particles, which conſequently attract the ſun in proportion to their reſpective maſſes; beſides, each body on the earth tends towards its centre proportionally to its maſs, it re-acts therefore on it, and attracts it in the ſame ratio. If that was not the caſe, and if any part of the earth, however ſmall, attracted another part without being attracted by it, the centre of gravity would move in ſpace, in virtue of the force of gravity, which is impoſſible.

The celeſtial phenomena, compared with the laws of motion, conduct us therefore to this great principle of nature, namely, that all the particles of matter attract each other in proportion to their maſſes, and inverſely as the ſquares of their diſtance.

Already we may perceive in this univerſal gravitation, the cauſe of the perturbations to which the heavenly bodies are ſubject; for the planets and comets being ſubject to the action of each other, they muſt deviate a little from the laws of the elliptic motion, which they would otherwiſe exactly follow, if they only obeyed the action of the ſun. The ſatellites alſo, deranged in their motions round their planets by their mutual action, and that of the ſun, deviate a little from theſe laws.

We perceive then that the particles of the heavenly bodies, united by their attraction, ſhould form a maſs nearly ſpherical; and that the reſult of their action at the ſurface of the body ſhould produce all the phenomena of gravitation.

We ſee moreover that the motion of rotation of the celeſtial bodies ſhould ſlightly alter their ſpherical figure, and flatten them at the poles; and then the reſulting force of all their mutual actions not paſſing through their centres of gravity, ſhould produce in their axes of rotation ſimilar motions to thoſe diſcovered by obſervation. Finally, we may perceive why the particles of the ocean, unequally acted on by the ſun and moon, ſhould have oſcillations ſimilar to the ebbing and flowing of the tides. But theſe different effects of the principle of gravitation muſt be particularly developed, to give it all the certainty of which phyſical truth is ſuſceptible.

It is in the univerſal application of this theory to all the known celeſtial phenomena, that the modern ſcience of phyſical aſtronomy conſiſts, a ſcience which owes its origin to Newton, and which has been cultivated by every eminent mathematician, from the time of that great philoſopher to the preſent day. It is to La Place that the merit muſt be given of having completed this theory, by ſhewing that there remains not a ſingle phenomenon that it is not capable of explaining: he juſtly obſerves, that there is no queſtion here of vague cauſes, which cannot be ſubmitted to analyſis, and which the imagination modifies at pleaſure, to accommodate them to the phenomena. The law of univerſal gravitation has this ineſtimable advantage, that it may be reduced to calculation, and by a compariſon of its reſults with obſervation, it preſents the moſt certain method of verifying its exiſtence; and ſo far are we from having to fear that new obſervations will diſprove this theory, we may be aſſured before hand that they will only confirm it more and more, and that its conſequences are equally certain as if they had actually been obſerved.

The aſtronomical phenomena produced by the mutual gravitation of the heavenly bodies, will be found in the different parts of this work. As each ſubject will be particularly treated under its appropriate article, ſee *Figure of the* EARTH; *Preceſſion of the* EQUINOXES; NUTATION *of the Earth's axis*; PERTURBATION *of the Planets, Moon,* and *Satellites*; TIDES, LIBRATION *of the Moon*, &c.

But as the inveſtigation of laws by which particles of matter gravitate to ſpheres and other ſolids cannot with propriety be referred to any other article, and as it forms ſo very eſſential a part of phyſical aſtronomy, we ſhall enter on the ſubject very fully. The more ſimple and eaſy inveſtigations of aſtronomy ſuppoſe the action to be confined to ſimple gravitating points; now as no ſuch points exiſt in nature, it becomes requiſite to conſider the effect which an aſſemblage of theſe points will produce when arranged in different forms. Newton, who firſt entered upon theſe ſpeculations, inveſtigated almoſt all the caſes which ſeem applicable to phyſical aſtronomy, but profeſſor Playfair has lately extended theſe reſearches, and has preſented a paper on the ſubject to the Philoſophical Society of Edinburgh, which would reflect honour on the firſt mathematicians of Europe. A few of the leading propoſitions of this excellent memoir, will follow the inveſtigation of the law of gravitation to a ſphere.

Of the gravitation of particles of matter to ſpheres, and other mathematical figures.

1. *A particle of matter placed within a ſphere of uniform denſity, remains in equilibrio.*

Let A L B M, *a l b m*, (*Plate* XV. *Aſtronomy, fig.* 124.) be two ſpherical ſurfaces, of which C is the common centre, and let the ſpace between them be filled with gravitating matter, uniformly denſe. Let *p* be a particle placed any where within this ſpherical ſhell, to every particle of which it gravitates with a force inverſely as the ſquare of its diſtance from it. This particle will have no tendency to move in any direction, becauſe its gravitation in any one direction is exactly balanced by an equal gravitation in the oppoſite direction.

Draw through p the two ſtraight lines $dp\varepsilon$, $ep\delta$, making a very ſmall angle at p. This may repreſent the ſection of a very ſlender double cone $dpe\delta p\varepsilon$, having p for the common vertex, and $de\delta\varepsilon$ for the diameter of the circular baſes. The gravitation of p to the matter in the baſe de is equal to its gravitation to the matter in the baſe $\delta\varepsilon$. For the number of particles in de is to the number in $\delta\varepsilon$, as the ſurface of the baſe de to that of the baſe $\delta\varepsilon$, that is, as de^2 to $\delta\varepsilon^2$, that is, as pd^2 to $p\delta^2$, that is, as the gravitation to a particle in $\delta\varepsilon$ to the gravitation to a particle in de. Therefore the whole gravitation to the matter in de, is the ſame with the whole gravitation to the matter in $\delta\varepsilon$: ſince it is alſo in the oppoſite direction, the particle p is in equilibrio. The ſame thing may be demonſtrated of the gravitation to the matter in qr and st, and in a ſimilar manner, of the gravitation to the matter in the ſections of the cones dpe, $\delta p\varepsilon$, by any other concentric ſurface. Conſequently, the gravitation to the whole matter contained in the ſolid $dqre$, is equal to the gravitation to the whole matter in the ſolid $\delta ts\varepsilon$, and the particle p is ſtill in equilibrio.

Now ſince the lines $dp\varepsilon$, $ep\delta$, may be drawn in any direction, and thus be made to occupy the whole ſphere, it is evident that the gravitation of p is balanced in every direction, and therefore it has no tendency to move in any direction, in conſequence of this gravitation to the ſpherical ſhell of matter comprehended between the ſurfaces A L B M and $albm$.

It is alſo evident, that this holds true with reſpect to all the matter comprehended between A L B M, and the concentric ſurface pnv paſſing through p; in ſhort p is in equilibrio in its gravitation, to all the matter more remote than itſelf from the centre of the ſphere, and appears as if it did not gravitate at all to any matter more remote from the centre.

We have ſuppoſed the ſpherical ſhell to be uniformly denſe. But p will ſtill be in equilibrio, although the ſhell be made up of concentric ſtrata of different denſities, provided that each ſtratum be uniformly denſe.

For ſhould we ſuppoſe, that in the ſpace comprehended between A L B M and pnv, there occurs a ſurface $albm$ of a different denſity from all the reſt, the gravitation to the intercepted portions qr and st are equal, becauſe thoſe portions are of equal denſity, and are proportioned to pq^2 and ps^2 inverſely. The propoſition may therefore be expreſſed in the following very general terms, "a particle placed any where within a ſpherical ſhell of gravitating matter, of equal denſity, at all equal diſtances from the centre, will be in equilibrio, and will have no tendency to move in any direction."

The equality of the gravitation to the ſurface ed, and to the ſurface $\varepsilon\delta$ is affirmed, becauſe the numbers of particles in the two ſurfaces are inverſely as the gravitations towards one in each.

For the very ſame reaſon, the gravitations towards the ſurfaces ed and qr and ts are all equal. Hence may be derived an elementary propoſition; which is of great uſe in all enquiries of this kind, namely,

If a cone, or pyramid $dp\varepsilon$, of uniform gravitating matter, be divided by parallel ſections de, qr, &c. the gravitation of a particle p in the vertex, to each of thoſe ſections, is the ſame, and the gravitations to the ſolids pqr, pde, $qder$, &c. are proportional to their lengths pq, pd, qd, &c. the firſt part of this propoſition is already demonſtrated. Now, conceive the cone to be thus divided into innumerable ſlices of equal thickneſs: it is plain that the gravitation to each of theſe is the ſame; and, therefore, the gravitation to the ſolid qpr, is to the gravitation to the ſolid $qder$, as the number of ſlices in the firſt, to the number of ſlices in the ſecond, that is, as pq, the length of the firſt, to qd, the length of the ſecond. The cone dpe was ſuppoſed extremely ſlender. This was not neceſſary for the demonſtration of the particular caſe where all the ſections were parallel; but in this elementary propoſition, the angle at p is ſuppoſed ſmaller than any aſſigned angle, that the cone or pyramid may be conſidered as one of the elements into which we may reſolve a body of any form. In this reſolution, the baſes are ſuppoſed, if not otherwiſe expreſsly ſtated, to be parallel, and perpendicular to the axes; indeed, they are ſuppoſed to be portions xr, ye, $z\varepsilon$, of ſpherical ſurfaces, having their centres in p: the ſmall portions xrq, yed, $z\varepsilon\delta$, &c. are held as inſignificant, vaniſhing in the ultimate ratios of the whole ſolids.

It is eaſy, alſo, to ſee that the equilibrium of p is not limited to the caſe of a ſpherical ſhell, but will hold true of any body compoſed of parallel ſtrata, or ſtrata ſo formed, that the lines pd, $p\delta$, are cut in the ſame proportion by the ſections de, qr, &c. In a ſpheroidal ſhell, for inſtance, whoſe inner and outer ſurfaces are ſimilar, and ſimilarly poſited ſpheroids, the particle p will be in equilibrio any where within it; becauſe, in this caſe, the lines $p\delta$ and ne are equal; ſo are the lines $p\varepsilon$ and od, the lines $t\delta$ and re, the lines $s\varepsilon$ and qd, &c.: in moſt caſes, however, there is but one ſituation of the particle p that inſures this equilibrium. But we may at the ſame time infer this very uſeful propoſition,

2. *If there be two ſolids, perfectly ſimilar, and of the ſame uniform denſity, the gravitation to each of theſe ſolids, by a particle ſimilarly placed on or in each, is proportional to any homologous lines of the ſolids.*

For, the ſolids being ſimilar, they may be reſolved into the ſame number of ſimilar pyramids ſimilarly placed in the ſolids. The gravitations to each of any correſponding pair of pyramids are proportional to the lengths of thoſe pyramids. Theſe lengths have the ſame proportion in every correſponding pair. Therefore, the abſolute gravitations to the whole pyramids of one ſolid have the ſame ratio to the abſolute gravitation to the whole pyramids of the other ſolid. And ſince the ſolids are ſimilar, and the particles are at the ſimilarly placed vertices of all the ſimilar and ſimilarly placed pyramids, the gravitation compounded of the abſolute gravitations to the pyramids of one ſolid, has the ſame ratio to the gravitation ſimilarly compounded of the abſolute gravitations to the pyramids of the other.

3. *The gravitation of an external particle to a ſpherical ſurface, ſhell, or entire ſphere, which is equally denſe at all equal diſtances from the centre, is the ſame as if the whole matter were collected in its centre.*

Let A L B M (*fig.* 124.) repreſent ſuch a ſphere, and let P be the external particle. Draw P A C B through C, the centre of the ſphere, and croſs it by L C M at right angles. Draw two right lines P D, P E, containing a very ſmall angle at P, and cutting the great circle A L B M, in D, E, D′, E′. About P, as a centre with the diſtance P C, deſcribe the arc C dm, cutting D P in d, and E P in e. About the ſame centre deſcribe the arc D O. Draw dF, eG, parallel to A B, and cutting L C in f and g. Draw C K perpendicular to P D, and dH, D δ, and I F φ, perpendicular to A B. Join C D and C F.

Now, let the figure be ſuppoſed to turn round the axis P B. The ſemi-circumference A L B will generate a complete ſpherical ſurface; the arc C dm will generate another ſpherical ſurface, having P for the centre; the ſmall

area

arcs D E, *d e*, F G, will generate rings, or zones, of thoſe ſpherical ſurfaces; D O will alſo generate a zone of a ſurface having P for its centre; *f g* and F I will generate zones of flat circular ſurfaces.

It is evident that the zones generated by D E and D O, (which we may call the zones D E, D O,) having the ſame radius D δ, are to each other as their reſpective breadths D E, D O. In like manner, the zones generated by *de*, *fg*, F I, F G, being all at the ſame diſtance from the axis A B, are alſo as their reſpective breadths *de*, *fg*, F I, F G. But the zone D O is to the zone *de*, as PD^2 to Pd^2: for D O is to *de*, as P D to P *d*, and the radius of rotation D δ is to the radius *d* H, alſo as P D to P *d*. The circumferences, deſcribed by D O and *de*, are, therefore, in the ſame proportion as P D to P *d*; therefore the zones being as their breadths, and as their circumferences jointly, are as PD^2 and Pd^2.

C K and *d* H, being the ſines of the ſame arc C *d*, are equal; therefore K D and *f* F, the halves of chords equally diſtant from the centre, are alſo equal; therefore the triangles C D K and C F *f* are equal and ſimilar. But C D K is ſimilar to E D O, for the right angles P D O and C D E are equal. Taking away the common angle C D O, the remainders C D K and E D O are equal. In like manner, C F *f* and G F I are ſimilar; and, therefore, (ſince C D K and C F *f* are ſimilar,) the elementary triangles E D O and G F I are ſimilar, and D O : D E = F I : G F. The abſolute gravitation, or tendency of P, to the zone D O, is equal to its abſolute gravitation to the zone *d e*, becauſe the number of particles in the firſt, is to the particles in the laſt, as PD^2 to Pd^2, that is, inverſely as the gravitation to a particle in the firſt, to the gravitation to a particle in the laſt; therefore let *c* repreſent the circumference of a circle, whoſe radius is 1. The ſurface of the zone generated by D O, will be $DO \times c \times D\delta$, and the gravitation to it will be $\frac{DO \times c \times D\delta}{PD^2}$, to which $\frac{de \times c \times dH}{Pd^2}$, or $\frac{de \times c \times dH}{PC^2}$, is equal. This expreſſes the abſolute gravitation to the zone generated by D O, this gravitation being exerted in the direction P D.

But it is evident that the tendency of P, ariſing from its gravitation to every particle in the zone, muſt be in the direction P C. The oblique gravitation muſt, therefore, be eſtimated in the direction P C, and muſt be reduced in the proportion of P *d* to P H. It is plain that P *d* : P H = *de* : *fg*, becauſe *d e* and *f g* are perpendicular to P *d* and P H; therefore the reduced, or central gravitation of P, to the zone generated by D O, will be expreſſed by $\frac{fg \times c \times dH}{PC^2}$.

But the gravitation to the zone generated by D O, is to the gravitation to the zone generated by D E, as D O to D E, that is, as F I (or *fg*) to F G. Therefore the central gravitation to the zone generated by D E, will be expreſſed by $\frac{FG \times c \times dH}{PC^2}$. Now, $FG \times c \times dH$ is the value of the ſurface of the zone generated by F G; and if all this matter were collected in C, the gravitation of P to it would be exactly $\frac{FG \times c \times dH}{PC^2}$, and it would be in the direction P C. Hence it follows, that the central gravitation of P to the zone generated by D E, is the ſame as its gravitation to all the matter in the zone generated by F G, if that matter were placed in C.

What has been demonſtrated reſpecting the arc D E, is true of every portion of the circumference. Each has a ſubſtitute F G, which being placed in the centre *c*, the gravitation of P is the ſame. If P T touch the ſphere in T, every portion of the arc T L B will have its ſubſtitute in the quadrant L B, and every part of the arc A T has its ſubſtitute in the quadrant A T L, as is eaſily ſeen. And hence it follows, that the gravitation of a particle, P, to a ſpherical ſurface, A L B M, is the ſame as if all the matter of that ſurface were collected in its centre.

We ſee alſo that the gravitation to the ſurface generated by the rotation of A T round A B is equal to the gravitation to the ſurface generated by T L B, which is much larger but more remote.

What we have now demonſtrated with reſpect to the ſurface generated by the ſemicircle A L B, is equally true with regard to the ſurface generated by any concentric ſemicircle, ſuch as *a l b*. It is true, therefore, with regard to the ſhell comprehended between thoſe two ſurfaces; for this ſhell may be reſolved into innumerable concentric ſtrata, and the propoſition may be affirmed with reſpect to each of them, and therefore with reſpect to the whole. And this will be ſtill true if the whole ſphere be thus occupied.

Laſtly, it follows that the propoſition is ſtill true, although theſe ſtrata ſhould differ in denſity, provided that each ſtratum is uniformly denſe in every part.

It may, therefore, be affirmed in the moſt general terms, that a particle, P, placed without a ſpherical ſurface, ſhell, or entire ſphere, equally denſe at equal diſtances from the centre, tends to the centre with the ſame force, as if the whole matter of the ſurface, ſhell, or ſphere were collected there.

This will be found to be a very important propoſition.

4. *The gravitation of an external particle to a ſpherical ſurface, ſhell, or entire ſphere, of uniform denſity at equal diſtances from the centre, is as the quantity of matter in that body directly; and as the ſquare of the diſtance from its centre inverſely.*

For, if all the matter were collected in its centre, the gravitation would be the ſame, and it would then vary in the inverſe duplicate ratio of the diſtance.

Cor. 1.—Particles placed on the ſurfaces of ſpheres of equal denſity, gravitate to the centres of thoſe ſpheres with forces proportional to the radii of the ſpheres.

For the quantities of matter are as the cubes of the radii. Therefore the gravitation *g* is as $\frac{d^3}{d^2}$, that is, as *d*.

Cor. 2.—The ſame thing holds true if the diſtance of the external particles from the centres of the ſpheres are as the diameters or radii of the ſpheres.

Cor. 3.—If a particle be placed within the ſurface of a ſphere of uniform denſity, its gravitation at different diſtances from the centre will be as thoſe diſtances. For, it will not be affected by any matter of the ſphere that is more remote from the centre, and its gravitation to what is leſs remote, is as its diſtance from the centre by the laſt Cor.

5. *The mutual gravitation of two ſpheres of uniform denſity in their concentric ſtrata, is in the inverſe duplicate ratio of the diſtance between their centres.*

For the gravitation of each particle in the ſphere A, is to the ſphere B, the ſame as if all the matter in B were collected at its centre. Suppoſe it ſo placed:

The gravitation of B to A will be the ſame as if all the matter in A were collected at its centre. Therefore it will be as d^2 inverſely. But the gravitation of A to B is equal to that of B to A. Therefore, &c.

The abſolute gravitation of two ſpheres whoſe quantities of matter are A and B, and *d* the diſtance of their centres, is $\frac{A \times B}{d^2}$. For the tendency of one particle of A to B, being the aggregate of its tendencies to every particle of B, is $\frac{B}{d^2}$. Therefore, the tendency of the whole of A to B muſt be $\frac{A \times B}{d^2}$. And the tendency of B to A is equal to that of A to B.

6. *But if the centripetal forces which tend to the different points of ſpheres are proportional to the ſimple diſtances from the attracted bodies, then the compounded force with which two ſpheres attract each other mutually, is as the diſtance between the centres of the ſpheres.*

Caſe 1.—Let A E B F (*fig.* 125.) be a ſphere; S its centre; P a particle attracted; P A S B the axis of the ſphere paſſing through the centre of the particle; E F, *e f*, two planes cutting the ſphere and perpendicular to the axis, and equidiſtant one on one ſide, the other on the other, from the centre of the ſphere; G and *g* the interſections of the planes and the axis; and H any point in the plane E F. The centripetal force of the point H on the particle P, exerted in the direction of the line P H, is as the diſtance P H; and the ſame exerted in the direction of the line P G, or towards the centre S, is as the length P G. Therefore, the force of all the points in the plane E F, (that is, of the whole plane) by which the particle P is attracted towards the centre S, is as the diſtance P G multiplied by the number of thoſe points, that is, as the ſolid contained under that plane E F, and the diſtance P G. And, in like manner, the force of the plane *e f*, by which the particle P is attracted towards the centre S, is as that plane multiplied into its diſtance P *g*; or as the equal plane E F multiplied into that diſtance P *g*; and the ſum of the forces of both planes is as the plane E F, multiplied into the ſum of the diſtances P G + P *g*, that is, as that plane multiplied into twice the diſtance P S of the centre and the particle; that is, as twice the plane E F, multiplied into the diſtance P S, or as the ſum of the equal planes E F + *e f* multiplied into the ſame diſtance. And by a ſimilar train of reaſoning, the forces of all the planes in the whole ſphere, equidiſtant on each ſide from the centre of the ſphere, are as the ſum of thoſe planes, multiplied into the diſtance P S, that is, as the whole ſphere, and the diſtance P S jointly.

Caſe 2.—Let the particle P now attract the ſphere A E B F, and, by the ſame reaſoning, it will appear that the force with which the ſphere is attracted is as the diſtance P S.

Caſe 3.—If another ſphere be now compoſed of innumerable particles P, and becauſe the force with which every particle is attracted is as the diſtance of the particle from the centre of the firſt ſphere, and as the ſame ſphere conjointly, and is therefore the ſame as if the whole proceeded from a ſingle particle ſituated in the centre of the ſphere; the entire force with which all the particles in the ſecond ſphere are attracted, that is, with which the whole ſphere is attracted, will be the ſame as if that ſphere were attracted by a force proceeding from a ſingle particle in the centre of the firſt ſphere, and is therefore proportional to the diſtance between the centres of the ſpheres.

Caſe 4.—Let the ſpheres attract each other mutually, and the force will be doubled, but the proportion will remain the ſame.

Caſe 5.—Let the particle P be placed within the ſphere A E B F, (*fig.* 126.) and becauſe the force of the plane *e f*, upon the particle, is as the ſolid contained under that plane and the diſtance *p g*; and the contrary force of the plane E F, is as the ſolid contained under that plane and the diſtance *p* G; the force compounded of both will be as the difference of the ſolids, that is, as the ſum of the equal planes multiplied into half the difference of the diſtances; that is, as that ſum multiplied into *p* S, the diſtance of the particle from the centre of the ſphere. And, by a ſimilar train of reaſoning, the attraction of all the planes E F, *e f*, throughout the ſphere, that is, the attraction of the whole ſphere is conjointly as the ſum of all the planes or as the whole ſphere, and as *p* S the diſtance of the particle from the centre of the ſphere.

Caſe 6.—And if a new ſphere be now compoſed of innumerable particles, ſuch as *p*, ſituated within the firſt ſphere A E B F, it may be proved, as before, that the attraction, whether ſingle of one ſphere towards the other, or mutual of both towards each other, will be as the diſtance *p* S of the centres.

7. *If the ſtructure of the ſpheres be diſſimilar and unequal, proceeding directly from the centre towards the circumference, but ſimilar and equal throughout every circumference, at equal diſtances from the centre, and if the attractive force be as the diſtance of the attracted body, then the entire force with which two ſpheres of this kind attract each other mutually is proportional to the diſtance between the centres of the ſpheres.*—This is demonſtrated from the preceding propoſition.

The above inveſtigations relate to the principal caſes of attraction, namely, when the centripetal forces decreaſe in a duplicate ratio, or increaſe in the ſimple ratio of the diſtance. And it is remarkable that both theſe ſuppoſitions cauſe bodies to revolve in conic ſections, and compoſe ſpherical bodies, whoſe centripetal forces obſerve the ſame law of increaſe or decreaſe, in the receſs from the centre, as the forces of the particles themſelves do.

8. *If a circle* A E B (*fig.* 127.) *be deſcribed round the centre* S, *and two circles* E F, *e f*, *be alſo deſcribed round the centre* P, *interſecting the former in* E *and e*, *and the line* P S *in* F *and f*; *and if* E D, *e d*, *be drawn perpendicular to* P S; *then if the diſtance of the arcs* E F, *e f*, *be ſuppoſed to be infinitely diminiſhed, the limiting ratio of the evaneſcent line* D *d* *to the evaneſcent line* F *f* *is the ſame as that of the line* P E *to the line* P S.

For if the line P *e* interſect the arc E F in *q*, and the right line E *e*, which coincides with the evaneſcent arc E *e*, be produced and meet the right line P S in T; and the perpendicular S G be drawn from S to P E, becauſe the triangles D T E, *d* T *e*, D E S, are ſimilar, D *d* will be to E *e* as D T to T E, or D S to E S; and becauſe the triangles E *e q*, E S G, are ſimilar, E *e* will be to *e q* or F *f* as E S to S G; and *ex æquo* D *d* is to F *f* as D E to S G; that is, (becauſe the triangles P D E, P G S, are ſimilar,) as P E to P S.

9. *If a ſuperficies, as* E F *f e* (*fig.* 128.) *be ſuppoſed to have its breadth infinitely diminiſhed, and that by its revolution round the axis* P S *it deſcribes a ſpherical concavo-convex ſolid to the ſeveral equal particles of which equal centripetal forces tend: then the force with which that ſolid attracts a particle placed at* P *is in a ratio compounded of the ratio of the ſolid* $DE^2 \times Ff$, *and the ratio of the force with which the given particle in the place* F *f* *would attract the ſame particle.*

For if the force be firſt conſidered of the ſpherical ſuperficies F E, which is generated by the revolution of the arc F E, and is interſected any where, as in *r*, by the line *d e*, the annular part of the ſuperficies generated by the revolution of the arc rE will be as the ſmall line Dd, the radius of the ſphere remaining the ſame; as Archimedes has demonſtrated in his book on the ſphere and cylinder. And the force of this ſuperficies exerted in the direction of the lines PE or Pr ſituated all round in the conical ſuperficies, will be as this annular ſuperficies itſelf; that is, as the line Dd, or, which is the ſame, as the rectangle under the given radius PE of the ſphere, and the line Dd; but that force, exerted in the direction of the line PS, tending to the centre S, will be leſs in the ratio of PD to PE, and therefore will be as $PD \times Dd$. If the line DF be now conſidered as divided into innumerable equal particles, each of which may be called Dd, then the ſuperficies FE will be divided into ſo many equal annuli, whoſe forces will be as the ſum of all the rectangles $PD \times Dd$; that is, as $\frac{1}{2}PF^2 - \frac{1}{2}PD^2$ and therefore as DE^2. Let now the ſuperficies FE be multiplied into the altitude Ff, and the force of the ſolid $EFfe$ exerted upon the particle P will be as $DE^2 \times Ff$: that is, if the force be given which any given particle, as Ff, exerts upon the particle P at the diſtance PF. But if that force be not given, the force of the ſolid $EFfe$ will be as the ſolid $DE^2 \times Ff$, and that force not given conjointly.

10. *If to the ſeveral equal parts of a ſphere* ABE *fig.* 129.) *deſcribed about the centre* S, *there tend equal centripetal forces; and if from the ſeveral points* D, *perpendiculars* D, E, *be drawn to the axis of the ſphere* AB, *in which a particle* P *is placed, meeting the ſphere in* E; *and if in theſe perpendiculars the lengths* D, N, *be taken as the quantity* $\frac{DE^2 \times PS}{PE}$, *and as the force which a particle of the ſphere ſituated in the axis exerts at the diſtance* PE *upon the particle* P *conjointly; then the whole force with which the particle* P *is attracted towards the ſphere is as the area* ANB, *comprehended under the axis of the ſphere* AB, *and the curve line* ANB, *the locus of the point* N.

For ſuppoſing the conſtruction in the laſt lemma and theorem to remain, let the axis of the ſphere AB be ſuppoſed to be divided into innumerable equal particles D, d, and the whole ſphere to be divided into ſo many ſpherical concavo-convex laminæ $EFfe$, and let the perpendicular dn be drawn. By the laſt theorem the force with which the laminæ $EFfe$, attracts the particle P, is as $DE^2 \times Ff$, and the force of one particle exerted at the diſtance PE or PF conjointly. But (by the laſt lemma) Dd is to Ff as PE to PS, and therefore Ff is equal to $\frac{PS \times Dd}{PE}$; and $DE^2 \times Ff$ is equal to $Dd \times \frac{DE^2 \times PS}{PE}$; and therefore the force of the laminæ $EFfe$, is as $Dd \times \frac{DE^2 \times PS}{PE}$, and the force of a particle exerted at the diſtance PF conjointly; that is, by the ſuppoſition, as $DN \times Dd$, or as the evaneſcent area $DNnd$. Therefore the forces of all the laminæ exerted upon the particle P are as the areas $DNnd$, that is, the ſphere will be as the whole area ANB.

Cor. 1.—Hence if the centripetal force tending to the ſeveral particles remain always the ſame at all diſtances, and DN be made as $\frac{DE^2 \times PS}{PE}$, the whole force with which the particle is attracted by the ſphere is as the area ANB.

Cor. 2.—If the centripetal force of the particles vary reciprocally as the diſtance of the particle attracted by it, and DN be made as $\frac{DE^2 \times PS}{PE^2}$, the force with which the particle P is attracted by the whole ſphere will be as the area ANB.

Cor. 3.—If the centripetal force of the particles vary reciprocally as the cube of the diſtance of the particle attracted by it, and DN be made as $\frac{DE^2 \times PS}{PE^4}$, the force with which the particle is attracted by the whole ſphere will be as the area ANB.

Cor. 4.—And univerſally of the centripetal force tending to the ſeveral particles of the ſphere be ſuppoſed to be reciprocally as the quantity V; and DN be made as $\frac{DE^2 \times PS}{PE \times V}$, the force with which a particle is attracted by the whole ſphere will be as the area ANB.

11. *Suppoſing every thing to remain as above, it is required to meaſure the area* ANB *fig.* 130

From the point P let the right line PH be drawn touching the ſphere in H; and having drawn HI perpendicular to the axis PAB, biſect PI in L, and PE^2 will be equal to $PS^2 \times SE^2 \times 2PSD$. But becauſe the triangles SPH, SHI, are ſimilar, SE^2 or SH^2 is equal to the rectangle PSI. Therefore PE^2 is equal to the rectangle contained under PS and $PS \times SI \times 2SD$; that is, under PS and $2LS \times 2SD$; that is, under PS and $2LD$. Moreover DE^2 is equal to $SE^2 - SD^2$, or $SE^2 - LS^2 + 2SLD - LD^2$, that is, $2SLD - LD^2 - ALB$. For $LS^2 - SE^2$, or $LS^2 - SA^2$, is equal to the rectangle ALB. Therefore if inſtead of DE^2 we write $2SLD - LD^2 - ALB$, the quantity $\frac{DE^2 \times PS}{PE \times V}$, which is as the length of the ordinate DN, will now reſolve itſelf into three parts, $\frac{2SLD \times PS}{PE \times V} - \frac{LD^2 \times PS}{PE \times V} - \frac{ALB \times PS}{PE \times V}$; where, if inſtead of V we write the inverſe ratio of the centripetal force, and inſtead of PE, the mean proportional between PS and $2LD$, thoſe parts will become the ordinates of ſo many curve lines, whoſe areas may be found by the common methods.

Ex. 1.—If the centripetal force tending to the ſeveral particles of the ſphere be reciprocally as the diſtance, inſtead of V write PE the diſtance, then $2PS \times LD$ for PE^2; and DN will become as $SL - \frac{1}{2}LD - \frac{ALD}{2LD}$. Suppoſe DN equal to the double $2SL - LD - \frac{ALB}{LD}$ and $2SL$ the given part of the ordinate drawn into the length AB will deſcribe the rectangular area $2SL \times AB$;; and the indefinite part LD drawn perpendicularly into the ſame length with a continued motion, according to ſuch a law that its motion in either direction may, by increaſing or decreaſing, remain always equal to the length LD, will deſcribe the area $\frac{LB^2 - LA^2}{2}$, that is the area $SL \times AB$; which taken from the former area $2SL \times AB$, leaves the area $SL \times AB$. But the third part $\frac{ALB}{LD}$, drawn in a ſimilar manner with a continued motion perpendicularly into the ſame length, will deſcribe the area of an hyperbola, which ſubtracted from the area $SL \times AB$ will leave ANB the area ſought. Whence this conſtruction of the problem ariſes. At the points L, A, B, (*fig.* 131.) erect the perpendiculars L *l*, A *a*, B *b*; making A *a* equal to L B, and B *b* equal L A. Making L *l* and L B aſſymptotes, deſcribe through the points *a*, *b*, the hyperbolic curve *a b*: and the chord *b a* being drawn, will encloſe the area *a b a* equal to the area required A N B.

Example 2.—If the centripetal force tending to the ſeveral particles of the ſphere be repicrocally as the cube of the diſtance, or, (which is the ſame thing,) as that cube applied to any given plane; ſubſtitute $\frac{PE^3}{2AS^2}$ for V, and $2PS \times LD$ for PE^2; and D N will become as $\frac{SL \times AS^2}{PS \times LD} - \frac{AS^2}{2PS} - \frac{ALB \times AS^2}{2PS \times LD^2}$; that is, (becauſe P S, A S, S I, are continually proportional,) as $\frac{LSI}{LD} - \frac{1}{2} SI - \frac{ALB \times SI}{2LD^2}$. If theſe three parts be then drawn into the length A B, the firſt, $\frac{LSI}{LD}$, will generate the area of an hyperbola; the ſecond, $\frac{1}{2}$ S I, the area $\frac{1}{2} AB \times SI$; the third, $\frac{ALB \times SI}{2LD^2}$, the area $\frac{ALB \times SI}{2LA} - \frac{ALB \times SI}{2LB}$, that is, $\frac{1}{2} AB \times SI$: from the firſt ſubtract the ſum of the ſecond and third, and there will remain A N B, the area ſought. Whence ariſes this conſtruction of the problem. At the points L, A, S, B, (*fig.* 132.) erect the perpendiculars L *l*, A *a*, S *s*, B *b*, of which ſuppoſe S *s* equal S I; and through the point *s*, to the aſſymptotes L *l*, L B, deſcribe the hyperbola *a s b*, meeting the perpendiculars A *a*, B *b*, in *a* and *b*, and the rectangle 2 A S I, ſubtracted from the hyperbolic area A *a s b* B, will leave A N B, the area required.

Example 3.—If the centripetal force, tending to the ſeveral particles of the ſphere, decreaſe in a quadruplicate ratio of the diſtance from the particles, ſubſtitute $\frac{PE^4}{2AS^3}$ for V, then $\sqrt{2PS + LD}$ for P E, and D N will become as $\frac{SI^2 \times SL}{\sqrt{2SI}} \times \frac{1}{\sqrt{LD^3}} - \frac{SI^2}{2\sqrt{2SI}} \times \frac{1}{\sqrt{LD}} - \frac{SI^2 \times ALB}{2\sqrt{2SI}} \times \frac{1}{\sqrt{LD^5}}$. Theſe three parts, drawn into the length A B, produce as many areas, namely, $\frac{2SI \times SL}{\sqrt{2SI}}$ into $\overline{\frac{1}{\sqrt{LA}} - \frac{1}{\sqrt{LB}}}$, $\frac{SI^2}{\sqrt{2SI}}$ into $\overline{\sqrt{LB} - \sqrt{LA}}$, and $\frac{SI^2 \times ALB}{3\sqrt{2SI}}$ into $\overline{\frac{1}{\sqrt{LA^3}} - \frac{1}{\sqrt{LB^3}}}$; and theſe, after the proper reduction, become $\frac{2SI^2 \times SL}{LI}$, SI^2, and $SI^2 + \frac{2SI^3}{3LI}$: and theſe, by ſubtracting the latter terms from the former, become $\frac{4SI^3}{3LI}$; therefore the entire force with which the particle P is attracted towards the centre of the ſphere, is as $\frac{SI^3}{PI}$, that is, reciprocally as $PS^3 \times PL$.

The attraction of a particle, ſituated within the ſphere, may be determined by the ſame method; but more expeditiouſly by the following theorem.

12. *If* S I, S A, S P, (*fig.* 133.) *be taken continually proportional, in a ſphere deſcribed round the centre* S, *with the radius* S A; *then the attraction of a particle within the ſphere, in any place* I, *is to its attraction, without the ſphere, in a place* P, *in a ratio compounded of the ſub-duplicate ratio of* I S, P S, *the diſtances from the centre, and the ſub-duplicate ratio of the centripetal forces tending to the centre in thoſe places,* P *and* I.

As, if the centripetal forces of the particles of the ſphere be reciprocally as the diſtances of the particle attracted by them, the force with which the particle ſituated at I is attracted by the entire ſphere, will be to the force with which it is attracted at P, in a ratio compounded of the ſub-duplicate ratio of the diſtance S I to the diſtance S P, and the ſub-duplicate ratio of the centripetal force in the place I, ariſing from any particle in the centre to the centripetal force in the place P, ariſing from the ſame particle in the centre; that is, in the ſub-duplicate ratio of the diſtances S I, S P, to each other reciprocally. Theſe two ſub-duplicate ratios compoſe the ratio of equality; and, therefore, the attractions in I and P, produced by the whole ſphere, are equal. By a ſimilar calculation, if the forces of the particles of the ſphere are reciprocally in a duplicate ratio of the diſtance, it will be found that the attraction in I is to the attraction in P, as the diſtance S P to the ſemi-diameter S A of the ſphere. If thoſe forces are reciprocally in a triplicate ratio of the diſtances, the attractions in I and P will be to each other as SP^2 to SA^2; if in a quadruplicate ratio, as SP^3 to SA^3. Therefore, ſince the attraction in P, in this laſt caſe, was found to be reciprocally as $PS^3 \times PI$, the attraction in I will be reciprocally as SA^3 into P I; that is, becauſe SA^3 is given reciprocally as P I; and the progreſſion is the ſame indefinitely. The demonſtration of this theorem is as follows:

Retaining the ſame conſtruction as above, and a particle being in any place P, the ordinate D N was found to be as $\frac{DE^2 \times PS}{PE \times V}$; therefore, if I E be drawn, that ordinate for any other place of the particle, as I, will become (ſubſtituting P S and P E for I S and I E) as $\frac{DE^2 \times IS}{IE \times V}$. Suppoſe the centripetal forces proceeding from any point of the ſphere, as E, to be to each other at the diſtances I E and P E, as PE^n to IE^n (where the number *n* denotes the index of the powers of P E and I E,) and thoſe ordinates will become as $\frac{PE^2 \times PS}{PE \times PE^n}$, and $\frac{PE^2 \times IS}{IE \times IE^n}$, whoſe ratio to each other is as $PS \times IE \times IE^n$ to $IS \times PE \times PE^n$. Becauſe S I, S E, S P, are continually proportional, the triangles S P E, S E I, are alike; and thence I E is to P E, as I S to S E, or S A. Subſtitute the ratio of I S to S A for the ratio of I E to P E, and the ratio of the ordinates becomes that of $PS \times IE^n$ to $SA \times PE^n$. But the ratio of P S to S A is ſub-duplicate of that of the diſtances P S, S I; and the ratio of IE^n to PE^n, (becauſe I E is to P E as I S to S A) is ſub-duplicate of that of the forces at the diſtances P S, I S; therefore the ordinates, and conſequently the areas which the ordinates deſcribe, and the attractions proportional to them, are in a ratio compounded of thoſe ſub-duplicate ratios.

13. *To find the force with which a particle, placed in the centre*

centre of a ſphere, is attracted towards any ſegment of that ſphere.

Let P (*fig.* 134.) be a particle in the centre of a ſphere, and R B S D a ſegment thereof contained between the plane R D S, and ſpherical ſuperficies R B S. Let D B be interſected in F by a ſpherical ſuperficies E F G, deſcribed from the centre P, and let the ſegment be divided into the parts B R E F G S, F E D G: let that ſurface be ſuppoſed not purely mathematical, but phyſical, having ſome but a very inconſiderable thickneſs: let that thickneſs be called O, and (by what Archimedes has demonſtrated) that ſuperficies will be as $\mathrm{PF} \times \mathrm{DF} \times \mathrm{O}$: let us ſuppoſe beſides, the attractive forces of the particles of the ſphere, to be reciprocally as that power of the diſtances of which n is the index; and the force with which the ſurface E F G attracts the body P will be as $\frac{\mathrm{DE}^2 \times \mathrm{O}}{\mathrm{PF}^n}$; that is, as $\frac{2\,\mathrm{DE} \times \mathrm{O}}{\mathrm{PF}^{n-1}} - \frac{\mathrm{DF}^2 \times \mathrm{O}}{\mathrm{PF}^n}$. Let the perpendicular F N, drawn into O, be proportional to this quantity, and the curvilinear area D B I, which the ordinate F N, drawn through the length D B, with a continued motion deſcribes, will be as the whole force with which the whole ſegment R B S D attracts the body P.

14. *To find the force with which a particle, placed without the centre of a ſphere, in the axis of any ſegment, is attracted by that ſegment.*

Let the body P, placed in the axis A D B, of the ſegment E B K (*fig.* 135.) be attracted by that ſegment: round the centre P, with the radius P E, let the ſpherical ſurface E F K be deſcribed; and let it divide the ſegment into two parts E B K F E and E F K D E. Let the force of the former part be found by Prop. 11. and, the force of the latter part by Prop. 13. and the ſum of the forces will be the force of the whole ſegment E B K D E.

Theſe are the principal propoſitions by which Newton has inveſtigated the nature of the attraction exerciſed by ſpherical bodies. In the thirteenth ſection of the Principia, the author ſhews the manner in which the law of attraction is inveſtigated for other bodies; the moſt intereſting reſults are contained in the following propoſitions.

Of the attractive forces of bodies which are not of a ſpherical figure.

15. *If a body be attracted by another, and its attraction be conſiderably ſtronger when it is contiguous to the attracting body, than when they are ſeparated from one another by a very ſmall interval; the forces of the particles of the attracting body decreaſe, as the attracted body recedes, in more than a duplicate ratio of the particles attracted.*

16. *If the forces of the particles, of which an attractive body is compoſed, decreaſe as the attracted body recedes, in a triplicate, or more than triplicate ratio of the diſtance from the particles, the attraction will be conſiderably ſtronger in the place of contact, than when the attracting and attracted bodies are ſeparated from each, though by the moſt minute interval.*

17. *If two bodies, ſimilar to each other, and conſiſting of matter equally attractive, attract ſeparately two particles, proportional to thoſe bodies, and in a ſimilar ſituation to them; the accelerative attractions of the particles towards the entire bodies will be as the accelerative attractions of the particles towards particles of the bodies proportional to the whole, and ſimilarly ſituated in them.*

18. *If the attractive forces of the equal particles of any body be as the diſtance of the places from the particles, the force of the whole body will tend to its centre of gravity; and will be the ſame with the force of a globe, conſiſting of ſimilar and equal matter, and having its centre in the centre of gravity.*

19. *If there be ſeveral bodies, conſiſting of equal particles, whoſe forces are as the diſtances of the places from each, the force compounded of all the forces by which any particle is attracted, will tend to the common centre of gravity of the attracting bodies; and will be the ſame as if theſe attracting bodies, preſerving their common centre of gravity, ſhould unite there, and be formed into a globe.*

20. *If a ſolid be plane on one ſide, and infinitely extended on all other ſides, and conſiſt of equal particles equally attractive, whoſe forces decreaſe, as they recede from the ſolid in the ratio of any power greater than the ſquare of the diſtances; and a particle placed towards either part of the plane is attracted by the force of the whole ſolid; then the attractive force of the whole ſolid, as it recedes from its plane ſuperficies, will decreaſe in the ratio of a power whoſe ſide is the diſtance of a particle from the plane, and is indeed leſs by three than the index of the power of the diſtances.*

Though the above propoſitions are ſufficient for all aſtronomical inveſtigations, yet there are many queſtions in natural philoſophy, particularly thoſe which relate to the attraction of mountains, which require that theſe enquiries ſhould be extended to a greater variety of caſes; and the following propoſitions form a part of the intereſting inveſtigations of profeſſor Playfair, as he has communicated them to the public, in the ſixth volume of the Edinburgh Tranſactions, as above-mentioned: they were ſuggeſted to the learned author by the experiments which have been made of late years, concerning the gravitation of terreſtrial bodies, particularly by Dr. Maſkelyne on the attraction of mountains, and by Mr. Cavendiſh, on the attraction of leaden balls, as has been deſcribed at length under the article DENSITY, to which the reader is referred.

I. *To find the ſolid into which a maſs of homogeneous matter muſt be formed, to attract a particle given in poſition with the greateſt force poſſible in a given direction.*

Let A (*fig.* 136.) be the particle given in poſition, A B the direction in which it is to be attracted; and A C B H a ſection of the ſolid required, by a plane paſſing through A B.

Since the attraction of the ſolid is a maximum by hypotheſis, any ſmall variation in the figure of the ſolid, provided the quantity of matter remain the ſame, will not change the attraction in the direction A B. If, therefore, a ſmall portion of matter be taken from any point C in the ſuperficies of the ſolid, and placed at D, another point in the ſame ſuperficies, there will be no variation in the force which the ſolid exerts on the particle A in the direction A B.

The curve A C B, therefore, is the locus of all the points, in which a body, being placed, will attract the particle A in the direction A B, with the ſame force. This condition is ſufficient to determine the nature of the curve A B C. From C any point in that curve, draw C E perpendicular to A B; then if a maſs of matter, placed at C be called m^3, $\frac{m^3}{\mathrm{AC}^2}$ will be the attraction of that maſs on A, in the direction A C, and $\frac{m^3 \times \mathrm{AE}}{\mathrm{AC}^3}$ will be its attraction in the direction A B: as this is conſtant, it will be equal to $\frac{m^3}{\mathrm{AB}^2}$, and, therefore, $\mathrm{AB}^2 \times \mathrm{AE} = \mathrm{AC}^3$.

All the ſections of the required ſolid, therefore, by planes paſſing through A B, have this property, that AC^3 = A.

$= AB^2 \times AE$; and as this equation is ſufficient to determine the nature of the curve to which it belongs, therefore all the ſections of the ſolid, by planes that paſs through A B, are ſimilar and equal curves; and the ſolid, in conſequence, may be conceived to be generated by the revolution of A C B, any one of thoſe curves, about A B as an axis.

The ſolid ſo generated may be called the *ſolid of greateſt attraction*, and the line A C B the *curve of equal attraction.*

II. *To find the equation between the co-ordinates of* A C B, *the curve of equal attraction.*

From C (*fig.* 136.) draw C E perpendicular to A B; let $AB = a$, $AE = x$, $EC = y$.

It has been found that $AB^2 \times AE = AC^3$, that is $a^2 x = (x^2 + y^2)^{\frac{3}{2}}$, or $a^4 x^2 = (x^2 + y^2)^3$, which is an equation to a line of the ſixth order.

To obtain y in terms of x, $x^2 + y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}}$, $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$ and $y = x^{\frac{1}{3}} \sqrt{a^{\frac{4}{3}} - x^{\frac{4}{3}}}$.

Hence $y = 0$, both when $x = 0$, and when $x = a$. Alſo, if x be ſuppoſed greater than a, y is impoſſible. No part of the curve, therefore, lies beyond B.

The parts of the curve on oppoſite ſides of the line A B are ſimilar and equal, becauſe the poſitive and negative values of y are equal. There is alſo another part of the curve on the ſide of A, oppoſite to B, ſimilar and equal to A C B; for the values of y are the ſame, whether x be poſitive or negative.

III. *The curve may be eaſily conſtructed without having recourſe to the value of y juſt obtained.*

Let $AB = a$ (*fig.* 136.) $AC = z$, and the angle $BAC = \varphi$. Then $AE = AC \times \text{coſ.}\ \varphi = z\ \text{coſ.}\ \varphi$, and ſo $a^2 z\ \text{coſ.}\ \varphi = z^3$, or $a^2\ \text{coſ.}\ \varphi = z^2$; hence $z = a \sqrt{\text{coſ.}\ \varphi}$.

From this formula a value of A C or z may be found, if φ or the angle B A C be given; and if it be required to find z in numbers, it may be conveniently calculated from this expreſſion. A geometrical conſtruction may alſo be eaſily derived from it. For if with the radius A B, a circle B F H be deſcribed from the centre A; if A C be produced to meet the circumference in F, and if F G be drawn at right angles to A B, then $\frac{AG}{AB} = \text{coſ.}\ \varphi$, and ſo $z = a \times \sqrt{\frac{AG}{AB}} = \sqrt{AB \times AG} = AC$.

Therefore, if from the centre A, with the diſtance A B, a circle B F H be deſcribed; and if a circle be alſo deſcribed on the diameter A B as A K B, then drawing any line A F from A, meeting the circle B F H in F, and from F letting fall F G the perpendicular on A B, interſecting the ſemicircle A K B in K; and if A K be joined, and A C made equal to A K, the point C is in the curve.

For $AK = \sqrt{AB \times AG}$, from the nature of the ſemi-circle, and therefore $AC = \sqrt{AB \times AG}$, which has been ſhewn to be a property of the curve. In this way a number of points of the curve may be determined; and the *ſolid of greateſt attraction* will be deſcribed, as already explained, by the revolution of this curve about the axis A B.

IV. *To find the area of the curve* A C B.

1. Let A C E, A F G (*fig.* 137.) be two radii indefinitely near to one another, meeting the curve A C B in C and F, and the circle deſcribed with the radius A B in E and G. Let $AC = z$ as before, the angle $BAC = \varphi$, and $AB = a$. Then $GE = a\dot{\varphi}$, and the area $AGE = \frac{1}{2} a^2 \dot{\varphi}$, and ſince $AE^2 : AC^2 :: \text{ſect.}\ AEG : \text{ſect.}\ ACF$, the ſector $ACF = \frac{1}{2} z^2 \dot{\varphi}$. But $z^2 = a^2\ \text{coſ.}\ \varphi$, whence the ſector $ACF = \frac{1}{2} z^2 \varphi$. But $z^2 = a^2\ \text{coſ.}\ \varphi$, (III.) whence the ſector A C F, or the fluxion of the area $ABC = \frac{1}{2} a^2 \dot{\varphi}\ \text{coſ.}\ \varphi$, and conſequently the area $ABC = \frac{1}{2} a^2\ \text{ſin.}\ \varphi$, to which no conſtant quantity need be added, becauſe it vaniſhes when $\varphi = 0$, or when the area A B C vaniſhes.

The whole area of the curve therefore is $\frac{1}{2} a^2$, or $\frac{1}{2} AB^2$; for when φ is a right angle $\text{ſin.}\ \varphi = 1$. Hence the area of the curve on both ſides of A B is equal to the ſquare of A B.

2. The value of x, when y is a maximum, is eaſily found. For when y, and therefore y^2, is a maximum, $\frac{2}{3} a^{\frac{4}{3}} - x^{\frac{1}{3}} = 2x$, or $3x^{\frac{4}{3}} = a^{\frac{4}{3}}$, that is, $x = \frac{a}{3^{\frac{3}{4}}} = \frac{a}{\sqrt[4]{27}}$.

Hence calling b the value of y when a maximum, $b^2 = a^{\frac{4}{3}} \times \frac{a^{\frac{2}{3}}}{27^{\frac{1}{6}}} - \frac{a^2}{27^{\frac{1}{2}}} = a^2 \left(\frac{27^{\frac{1}{3}} - 1}{27^{\frac{1}{2}}}\right) = \frac{2a^2}{\sqrt{27}}$, and ſo $b = a \frac{\sqrt{2}}{\sqrt[4]{27}}$, and therefore $a : b :: \sqrt[4]{27} : \sqrt{2}$, or as 11 : 7 nearly.

3. It is material to obſerve, that the radius of curvature A is infinite: for ſince $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, $\frac{y^2}{x} = \frac{a^{\frac{4}{3}}}{x^{\frac{1}{3}}} - x$.

But when x is very ſmall, or y indefinitely near to A, $\frac{y^2}{x}$ becomes the diameter of the circle, having the ſame curvature with A C B at A; and when x vaniſhes, this value of $\frac{y^2}{x}$, or $\frac{a^{\frac{4}{3}}}{x^{\frac{1}{3}}} - x$ becomes infinite, becauſe of the diviſor $x^{\frac{1}{3}}$ being in that caſe $= 0$. The diameter, therefore, and the radius of curvature at A, are infinite. In other words, no circle, having its centre in A B produced, and paſſing through A, can be deſcribed with ſo great a radius, but that at the point A it will be within the curve of equal attraction.

The ſolid of greateſt attraction then, at the extremity of its axis, where the attracted particle is placed, is exceedingly flat, approaching more nearly to a plane than the ſuperficies of any ſphere can do, however great its radius.

4. To find the radius of curvature at B, the other extremity of the axis, ſince $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, if we divide by $a - x$, we have $\frac{y^2}{a - x} = \frac{a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2}{a - x}$.

But at B, when $a - x$, or the abſciſſa reckoned from B vaniſhes, $\frac{y^2}{a - x}$ is the diameter of the circle, having the ſame curvature with A C B in B. But when $a - x = 0$, or $a = x$ both the numerator and denominator of the fraction $\frac{a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2}{a - x}$ vaniſhes, ſo that its ultimate value does not appear. To remove this difficulty, let $a - x = z$, or $x = a - z$, then we have $y^2 = (a - z)^{\frac{2}{3}} - (a - z)^2$.

But when z is extremely ſmall, its powers higher than the firſt may be rejected; and therefore $(a - z)^{\frac{2}{3}} = a^{\frac{2}{3}} \left(1 - \frac{z}{a}\right)^{\frac{2}{3}} = a^{\frac{2}{3}} \left(1 - \frac{2z}{3u} \&c.\right)$ Therefore the equation to the curve becomes in this caſe, $y^2 = a^{\frac{4}{3}} \times a^{\frac{2}{3}} \left(1 - \frac{2z}{3a}\right) - a^2 + 2az = a^2 - \frac{2}{3} az - a^2 + 2az = \frac{4}{3} az$.

Hence $\frac{y^2}{2z}$, or the radius of curvature at $B = \frac{2}{3}a$. The curve therefore at B falls wholly without the circle B K A, deſcribed on the diameter A B, as its radius of curvature is greater. This is alſo evident from the conſtruction.

V. *To find the force with which the ſolid above defined attracts the particle* A *in the direction* A B.

Let B (*fig.* 137.), be a point indefinitely near to B, and let the curve A *c b* be deſcribed ſimilar to A C B; through C draw C *c* D perpendicular to A B, and ſuppoſe the figure thus conſtructed to revolve about A B; then each of the curves A C B, A *c b*, will generate a ſolid of greateſt attraction; and the exceſs of the one of theſe ſolids above the other, will be an indefinitely thin ſhell, the attraction of which is the variation of the attraction of the ſolid A C B when it changes into A *c b*.

Again, by the line D C, when it revolves along with the reſt of the figure about A B, a circle will be deſcribed; and by the part C *c*, a circular ring, on which, if we ſuppoſe a ſolid of indefinitely ſmall altitude to be conſtituted, it will make the element of the ſolid ſhell A C *c*. Now the attraction exerted by this circular ring upon A will be the ſame as if all the matter of it were united in the point C, and the ſame, therefore, as if it were all united in B.

But the circular ring generated by C *c* is $= \pi\,(DC^2 - Dc^2) = 2\pi\, DC \times Cc$. Now, $2\,DC \times Cc$ is the variation of y^2, or DC^2, while D C paſſes into D *c*, and the curve B C A into the curve *b c* A; that is, $2\,DC \times Cc$ is the fluxion of y^2, or of $a^{\frac{4}{3}}x^{\frac{2}{3}} - x^2$, taken on the ſuppoſition that x is conſtant and a variable, namely $\frac{4}{3}a^{\frac{1}{3}}\dot{a} \times x^{\frac{2}{3}}$. Therefore the ſpace generated by $Cc = \frac{4\pi}{3}a^{\frac{1}{3}}x^{\frac{2}{3}}\dot{a}$.

If this expreſſion be multiplied by $\dot{x}$, we have the element of the ſhell $= \frac{4\pi}{3}a^{\frac{1}{3}}x^{\frac{2}{3}}\dot{a}\dot{x}$.

In order to have the ſolidity of the ſhell A C B *b c*, the above expreſſion muſt be integrated relatively to x, that is, ſuppoſing only x variable, and it is then $\frac{3}{5} \times \frac{4\pi}{3}a^{\frac{1}{3}}x^{\frac{5}{3}}\dot{a} + C$.

But $C = 0$, becauſe the fluent vaniſhes when x vaniſhes, therefore the portion of the ſhell A C $c = \frac{4}{5}x^{\frac{5}{3}}a^{\frac{1}{3}}\dot{a}$, and when $x = a$ the whole ſhell $= \frac{4\pi}{5}a^2\dot{a}$.

Now, if the whole quantity of matter in the ſhell were united at B, its attractive force exerted on A would be the ſame with that of the ſhell, therefore the whole force of the ſhell $= \frac{4\pi}{5}\dot{a}$. The ſame is true for every other indefinitely thin ſhell, into which the ſolid may be ſuppoſed to be divided; and, therefore, the whole attraction of the ſolid is equal to $\int\frac{4\pi}{5}\dot{a}$, ſuppoſing a variable, that is, $= \frac{4\pi}{5}a$.

Hence we may compare the attraction of this ſolid with that of a ſphere of which the axis is A B, for the attraction of that ſphere $= \frac{\pi}{6}a^3 \times \frac{4}{a^2} = \frac{2\pi}{3} \times a$: the attraction of the ſolid A D B H (*fig.* 136), is, therefore, to that of the ſphere on the ſame axis as $\frac{4\pi}{5}a$ to $\frac{2\pi}{3}a$, or as 6 to 5.

VI. *To find the content of the ſolid* A D B H, we need only integrate the fluxionary expreſſion for the content of the ſhell, namely, $\frac{4\pi}{5}a^2\dot{a}$. We have then $\frac{4\pi}{15}a^3 =$ the content of the ſolid A D B H. Since the ſolidity of the ſphere on the axis A is $= \frac{\pi}{6}a^3$, the content of the ſolid A D B H is to that of the ſphere on the ſame axis as $\frac{4\pi}{15}a^3$ to $\frac{\pi}{6}a^3$; that is, as $\frac{4}{15}$ to $\frac{1}{6}$, or as 8 to 5.

VII. *Laſtly, to compare the attraction of this ſolid with the attraction of a ſphere of equal bulk.*—Let $m^3 =$ any given maſs of matter formed into the ſolid A D B H; then for determining A B, we have this equation $\frac{4\pi}{15}a^3 = m^3$, and $a = m^3\sqrt{\frac{15}{4\pi}}$; and, therefore, alſo, the attraction of the ſolid, $\left(\text{which is } \frac{4\pi}{5}a\right) = \frac{4\pi}{5}m^3\sqrt{\frac{15}{4\pi}} = m\left(\frac{4\cdot5^{\frac{1}{3}}\cdot3^{\frac{1}{3}}\cdot\pi^{\frac{2}{3}}}{4\cdot5^{\frac{1}{3}}}\right) = m\left(\frac{4^{\frac{2}{3}}\cdot3^{\frac{1}{3}}\cdot\pi^{\frac{2}{3}}}{5^{\frac{2}{3}}}\right) = m\,\frac{\sqrt[3]{48\pi}}{25}$.

Again, if m^3 be formed into a ſphere, the radius of that ſphere $= m^3\frac{\sqrt{3}}{4\pi}$, and the attraction of it on a particle at its ſurface $\frac{m^3}{m^2\left(\frac{3}{4\pi}\right)^{\frac{2}{3}}} = m\frac{(16\pi^2)^{\frac{1}{3}}}{9^{\frac{1}{3}}}$.

Hence the attraction of the ſolid A D B H, is to that of a ſphere equal to it, as $m\left(\frac{48}{25}\pi^2\right)^{\frac{1}{3}}$ to $m\left(\frac{16}{9}\pi^2\right)^{\frac{1}{3}}$; that is, as $(27)^{\frac{1}{3}}$ to $(25)^{\frac{1}{3}}$, or as 3 to the cube root of 25.

The ratio of 3 to $\sqrt[3]{25}$, is nearly that of 3 to $3 - \frac{2}{27}$, or of 81 to 79; and this is therefore alſo nearly equal to the ratio of the attraction of the ſolid A D B H, to that of a ſphere of equal magnitude.

VIII.—*It has been ſuppoſed in the preceding inveſtigation, that the particle on which the ſolid of greateſt attraction exerts its force, is in contact with that ſolid. Let it now be ſuppoſed, that the diſtance between the ſolid and the particle is given; the ſolid being on one ſide of the plane and the particle at a given diſtance from the ſame plane on the oppoſite ſide. The maſs of matter which is to compoſe the ſolid being given, it is required to conſtruct the ſolid.*

Let the particle to be attracted be at A (*fig.* 137), from A draw A A′ perpendicular to the given plane, and let E F be any ſtraight line in that plane drawn through the point A′, it is evident that the axis of the ſolid required muſt be in A A′ produced. Let B be the vertex of the ſolid, then it will be demonſtrated as has been done above, that this ſolid is generated by the revolution of the curve of *equal attraction*, that of which the equation is $(y^2 = a^{\frac{4}{3}}x^{\frac{2}{3}} - x^2)$ about the axis of which one extremity is at A, and of which the length muſt be found from the quantity of matter in the ſolid.

The ſolid required then, is a ſegment of the ſolid of greateſt attraction, having B for its vertex, and a circle of which A′ E or A′ F is the radius, for its baſe.

To find the ſolid content of ſuch a ſegment, C D being $= y$, and $AC = x$, we have $y^2 = a^{\frac{4}{3}}x^{\frac{2}{3}} - x^2$, and $\pi y^2\dot{x} = \pi a^{\frac{4}{3}}x^{\frac{2}{3}}\dot{x} - \pi x^2\dot{x} =$ the cylinder, which is the element of the ſolid ſegment.

Therefore $\int\pi y^2\dot{x}$, or the ſolid ſegment intercepted between B and D, muſt be $\frac{3}{5}\pi a^{\frac{4}{3}}x^{\frac{5}{3}} - \frac{1}{3}\pi x^3 + C$. This muſt vaniſh when $x = a$, or when C comes to B, and therefore

fore $C = \frac{4\pi}{15} a^3$. The ſegment therefore intercepted between B and C, the line A C being x, is $\frac{4\pi}{15} a^3 - \frac{3\pi}{5} a^{\frac{4}{3}} x^{\frac{5}{3}} + \frac{\pi}{3} x^3$.

This alſo gives $\frac{4\pi}{15} a^3$, for the content of the whole ſolid, when $x = 0$, the ſame value that was found by another method at VI.

Now, if we ſuppoſe x to be $=$ A A′, and to be given $= b$, the ſolid content of the ſegment becomes $\frac{4\pi}{15} a^3 - \frac{3}{5}\pi a^{\frac{4}{3}} b^{\frac{5}{3}} + \frac{\pi}{3} b^3$ which muſt be made equal to the given ſolidity, which we ſhall ſuppoſe m^3, and from this equation a, which is yet unknown, is to be determined. If then for $a^{\frac{1}{3}}$ we put u, we have $\pi (\frac{4}{15} u^9 - \frac{3}{5} b^{\frac{5}{3}} u^4 - \frac{1}{3} b^3) = m^3$, or $\frac{4}{15} u^9 - \frac{3}{5} b^{\frac{5}{3}} u^4 = \frac{m^3}{\pi} - \frac{1}{3} b^3$, and $u^9 - \frac{9}{4} b^{\frac{5}{3}} u = \frac{15 m^3}{4\pi} - \frac{15}{12} b^3$.

The ſimpleſt way of ſolving this equation would be by the rule of falſe poſition. In ſome particular caſes it may be reſolved more eaſily; thus, if $\frac{15 m^3}{\pi} - \frac{15}{12} b^3 = 0$, $u^9 - \frac{9}{4} b^{\frac{5}{3}} u^4 = 0$, and $u^5 = \frac{9}{4} b^{\frac{5}{3}}$ that is $a^{\frac{5}{3}} = \frac{9}{4} b^{\frac{5}{3}}$, or $a = b \times (\frac{9}{4})^{\frac{3}{5}} = b \sqrt[5]{\frac{729}{64}}$.

IX.—1. *If it be required to find the equation to the ſuperficies of the ſolid of greateſt attraction, and alſo to the ſections of its parallel to any plane paſſing through the axis; this can readily be done by help of what has been demonſtrated above.*

Let A H B (*fig.* 138), be a ſection of the ſolid, by a plane paſſing through A B its axis. Let G be any point in the ſuperficies of the ſolid, G F a perpendicular from G on the plane A H B, and F E a perpendicular from F on the axis. Let A E $= x$, E F $= z$, F G $= v$, then x, z, and v are the three co-ordinates by which the ſuperficies is to be defined. Let A B $= a$, E H $= y$, then from the nature of the curve A H B, $y^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$. But, becauſe the plane G E H is at right angles to A B, G and H are in the circumference of a circle of which E is the centre; ſo that G E $=$ E H $= y$. Therefore $EF^2 + FG^2 = EH^2$, that is $z^2 + v^2 = y^2$, and by ſubſtitution for y^2 in the former equation, $z^2 + v^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, or $(x^2 + z^2 + v^2) = a^4 x^2$ which is the equation to the ſuperficies of the ſolid of greateſt attraction.

2. If we ſuppoſe E F, that is z, to be given $= b$, and the ſolid to be cut by a plane through F G and C D (C D being parallel to A B) making on the ſurface of the ſolid the ſection D G C; and if A K be drawn at right angles to A B, meeting D C in K, then we have, by writing b for z in either of the preceding equations, $b^2 + v^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2$, and $v^2 = a^{\frac{4}{3}} x^{\frac{2}{3}} - x^2 - b^2$ for the equation to the curve D G C, the co-ordinates being G F and F K, becauſe F K is equal to A E or x.

This equation alſo belongs to a curve of equal attraction; the plane in which that curve is being parallel to A B, the line in which the attraction is eſtimated, and diſtant from it by the ſpace b.

Inſtead of reckoning the abſciſſa from K, it may be made to begin at C. If A E or C K $= b$, then the value of b is determined from the equation $b^2 = a^{\frac{4}{3}} b^{\frac{2}{3}} - b^2$, and if $x = b + u$, u being put for C F, $v^2 = a^{\frac{4}{3}} (b + u)^{\frac{2}{3}} - (b + u)^2 - a^{\frac{4}{3}} b^{\frac{2}{3}} + b^2$, or $v^2 + (b + u)^2 + b^2 = a^{\frac{4}{3}} (b + u)^{\frac{2}{3}}$, or $(v^2 + (b + u)^2 + b^2)^3 = a^4 (b + u)^2$.

When b is equal to the maximum value of the ordinate E H (IV. 2) the curve C D G goes away into a point; and if b be ſuppoſed greater than this, the equation to the curve is impoſſible.

X.—*The ſolid of greateſt attraction may be found, and its properties inveſtigated, in the way that has now been exemplified, whatever be the law of the attractive force. It will be ſufficient in any caſe to find the equation of the generating curve, or the curve of equal attraction.*

Thus, if the attraction, which the particle C (*fig.* 136.) exerts on the given particle at A, be inverſely as the m power of the diſtance, or as $\frac{1}{AC^m}$, then the attraction in the direction A E will be $\frac{AE}{AC^{m+1}}$, and if we make this $= \frac{1}{AB^m}$, we have $\frac{AE}{AC^{m+1}} = \frac{1}{AB^m}$, or making A E $= x$, E C $= y$, and A B $= a$, as before $\frac{x}{(x^2 + y^2)^{\frac{m+1}{2}}} = \frac{1}{a^m}$, or $a^m x = (x^2 + y^2)^{\frac{m+1}{2}}$ and $x^2 + y^2 = \frac{2m}{a^{m+1}} \frac{2}{x^{m+1}}$, or $y^2 = \frac{2m}{a^{m+1}} \frac{2}{x^{m+1}} - x^2$.

If $m = 1$, or $m + 1 = 2$, this equation becomes $y^2 = ax - x^2$, being that of a circle of which the diameter is A B. If, therefore, the attracting force were inverſely as the diſtance, the ſolid of greateſt attraction would be a ſphere.

If the force be inverſely as the cube of the diſtance, or $m = 3$, and $m + 1 = 4$, the equation is $y^2 = a^{\frac{3}{2}} x^{\frac{1}{2}} - x^2$, which belongs to a line of the fourth order.

If $m = 4$, and $m + 1 = 5$, the equation is $y^2 = a^{\frac{8}{5}} x^{\frac{2}{5}} - x^2$, which belongs to a line of the tenth order.

In general, if m be an even number, the order of the curve is $m + 1 \times 2$; but if m be an odd number, it is $m + 1$ ſimply.

In the ſame manner that the ſolid of greateſt attraction has been found, may a great claſs of ſimilar problems be reſolved. Whenever the property that is to exiſt in the greateſt or leaſt degree belongs to all the points of a plane figure, or to all the points of a ſolid, given in magnitude, the queſtion is reduced to the determination of the locus of a certain equation, as in the preceding example.

Let it, for inſtance, be required to find a ſolid given in magnitude, ſuch, that from all the points in it, ſtraight lines being drawn to any number of given points, the ſum of the ſquares of the lines ſo drawn ſhall be a *minimum.* It will be found, by reaſoning, as in the caſe of the ſolid of greateſt attraction, that the ſuperficies bounding the required ſolid muſt be ſuch, that the ſum of the ſquares of the lines drawn from any point in it, to all the given points, muſt be always of the ſame magnitude. Now, the ſum of the ſquares of the lines drawn from any point, to all the given points, may be ſhewn by plane geometry, to be equal to the ſquare of the line drawn to the centre of gravity of theſe given points, multiplied by the number of points together with a given ſpace. The line, therefore, drawn from any point in the required ſuperficies, to the centre of gravity of the given points, is given in magnitude, and therefore the ſuperficies is that of a ſphere, having for its centre the centre of gravity of the given points.

The magnitude of the ſphere is next determined from the condition that its ſolidity is given.

In general, if x, y and z are three rectangular co-ordinates, that determine the poſition of any point of a ſolid given in magnitude, and if the value of a certain function φ of x, y, and z be computed for each point of the ſolid, and if the ſum of all theſe values of φ added together be a maximum or a minimum, the ſolid is bounded by a ſuperficies, in which the function φ is every where of the ſame magnitude. That is, if the triple integral $\int \dot{x} \int \dot{y} \int \varphi \dot{z}$ be the greateſt or leaſt poſſible, the ſuperficies bounding the ſolid is ſuch, that $\varphi = A$, a conſtant quantity.

The ſame holds of plane figures. The propoſition is then more ſimple, as there are only two co-ordinates, ſo that $\int \dot{x} \int \varphi \dot{z}$ is the quantity that is to be a maximum or minimum, and the line bounding the figure is defined by the equation $\varphi = A$.

All the queſtions therefore that come under this deſcription, though they belong to an order of problems, which requires in general the application of one of the moſt refined inventions of new geometry, the *calculus variationum*, form a particular diviſion, admitting of ſolution by much more ſimple means, and directly reducible to the conſtruction of loci.

In theſe problems alſo, the ſynthetical demonſtration will be found extremely ſimple. In the inſtance of the ſolid of greateſt attraction, this holds remarkably. Thus it is obvious, that (*fig.* 136.) any particle of matter placed within the curve A C B H, will attract the particle at A in the direction A B, leſs than any of the particles in that curve, and that any particle of matter within the curve will attract the particle at A more than any particle in the curve, and more, *a fortiori*, than any particle without the curve. The ſame is true of the whole ſuperficies of the ſolid. Now if the figure of the ſolid be any how changed while its quantity of matter remains the ſame, as much matter muſt be expelled from within the ſurface, at ſome one place C, as is accumulated without the ſurface, at ſome other point H. But the action of any quantity of matter within the ſuperficies A C B H on A is greater than the action of the ſame without the ſuperficies A C B H. The ſolid A C B H therefore by any change of its figure muſt loſe more attraction than it gains. Thus is its attraction not diſtinguiſhed by every ſuch change, and therefore it is itſelf the ſolid of greateſt attraction.

Among a number of propoſitions which the limits of our work do not permit us to notice, it is propoſed, "to determine the oblate ſpheroid of a given ſolidity, which ſhall attract a particle at its pole with the greateſt force." And it appears that the gravitation at the pole of an oblate ſpheroid is not a maximum, until the excentricity of the generating ellipſe vaniſh, and the ſpheroid paſs into a ſphere. When a ſphere paſſes into an oblate ſpheroid its attraction varies at firſt exceeding ſlowly, and continues to do ſo till its oblateneſs, or excentricity, becomes very great.

The cone of greateſt attraction has the radius of its baſe nearly double that of its altitude, and the attraction of the cone, when a maximum, is about $\frac{4}{5}$ the attraction of a ſphere of equal ſolidity.

Of all the cylinders given in maſs or quantity of matter, that which attracts a particle at the extremity of its axis with the greateſt force is when the radius of the baſe of the cylinder is to the altitude as five to eight nearly, and it appears that the attraction of the cylinder, even when its form is the moſt advantageous, does not exceed that of a ſphere of the ſame ſolid content, by more than a hundred and eighty-third part.

A ſemi-cylinder given in magnitude, attracts a particle ſituated in the centre of its baſe, with the greateſt force poſſible, in the direction of a line biſecting the baſe, when the altitude of the ſemi-cylinder is to the radius of its baſe as 125 to 216.

Gravitation, *Centre of.* See Center.

Gravitation, *Line of.* See Line.

Gravitation, *Plane of.* See Plane.

GRAVITY, Terrestrial, is that force by which all bodies are continually urged towards the centre of the earth. It is in conſequence of this force that a body cannot remain at reſt on the ſurface of the earth, without exerciſing a preſſure either on ſome intermediate body, or on that portion of the ſurface of the earth which ſuſtains it; and the intenſity of this force is meaſured by the degree of preſſure, produced by a given maſs. The tenſion of a ſtring, by which a weight is ſuſpended, ariſes from the force of gravity. The ſpring ſteelyard, an inſtrument ſold at the ſhops for weighing, is extremely well adapted to illuſtrate the effect of the force of gravity; the ſuſpended ſubſtance draws out a ſcale by overcoming the reſiſtance of the ſpring. Theſe machines are not capable of great exactneſs, but if an inſtrument of this kind could be made with ſufficient accuracy, the alteration of the ſcale, (the weight remaining the ſame,) would ſhew any change in the force of gravity; and we might, by taking this apparatus to the ſummit of a high mountain, obſerve whether any change took place in the force of gravity by ſuch an operation. We meaſure likewiſe the force of gravity by the time which a body, ſuffered to deſcend freely from a ſtate of reſt, employs to fall through a given ſpace, or (as has been explained under Dynamics) by the velocity which a body, thus falling, acquires at the end of a given time. Thus a body, falling freely, during the interval of one ſecond, acquires a velocity of $32\frac{1}{6}$, that is, it would ſtrike an obſtacle with the ſame force as another body would of the ſame maſs, which was moving uniformly with the velocity of $32\frac{1}{6}$ per ſecond.

The denſity of the earth being about 2.5 that of water, we infer that the force of gravity of a ſphere, 8000 miles in diameter, and whoſe ſpecific gravity is twice and a half that of water, would attract a particle of matter placed juſt without its ſurface, in ſuch a manner as to cauſe it to move towards its centre, $16\frac{1}{12}$ feet in one ſecond.

It is, however, to be obſerved, that it is only at the pole that the *whole* force of the earth's gravity is actually exerted on a particle of matter: at every other part of the earth's ſurface, the force of gravity is diminiſhed by the motion of rotation, which producing a centrifugal force, oppoſite in its tendency to that of the force of gravity, diminiſhes the effect of the latter as we recede from the pole and approach the equator. But, beſides this, there is another cauſe which contributes in a very remarkable manner to modify the force of gravity at different points of the earth's ſurface, which is the elliptic figure of the earth.

The equatorial regions being more elevated than the polar, are more removed from the influence of the central attraction. Both theſe circumſtances, and their effects, muſt be attended to when we propoſe to make any very accurate computation of the force of terreſtrial gravity.

The diminution of gravity ariſing from the elliptic figure is nearly equal to the product of the $\frac{1}{289}$th part of the force of gravity, by the ſquare of the coſine of the latitude. The centrifugal force diminiſhes the force of gravity in the ſame proportion; thus by the combination of theſe two cauſes, the diminution of gravity from the pole to the equator is equal 0.00694 multiplied by the ſquare of the coſine of the latitude, the force of gravity at the equator being taken as unity.

The moſt exact inſtrument we poſſeſs, for meaſuring the intenſity of the force, is the pendulum, whoſe oſcillations are immediately accelerated or retarded by the ſlighteſt alteration in the force of gravity, and it is only by means of this inſtrument that we are enabled to infer with preciſion, the exact ſpace that a heavy body falls through in one ſecond of time.

GRAVITY, *The Nature of.*—Of the nature of gravitation, or the force of gravity, nothing more is known, than that it is apparently an eſſential property of matter, or, at leaſt, of all matter that hitherto has become the object of human inveſtigation; for Newton was not diſpoſed to believe but that matter might exiſt which was not endowed with this property, and ſuggeſts the ſuppoſition that it is cauſed by the agency of an elaſtic medium pervading all ſpace. This medium, he ſuppoſes, to be much rarer within the denſe bodies of the ſun, the ſtars, the planets, and the comets, than in the empty celeſtial ſpaces between them, and to grow more and more denſe at greater diſtances from them, ſo that all theſe bodies are naturally forced towards each other by the exceſs of preſſure. Upon this ſuppoſition, Dr. Young remarks, in his Lectures, that the effects of gravitation might be produced by a medium thus conſtituted, if its particles were repelled by all material ſubſtances with a force decreaſing like other repulſive forces, ſimply as the diſtances increaſe; its denſity would then be every where ſuch as to produce the appearance of an attraction, varying like that of gravitation. Such an ethereal medium would, therefore, have the advantage of ſimplicity, in the original law of its action, ſince the repulſive force, which is known to belong to all matter, would be ſufficient, when thus modified, to account for the principal phenomena of attraction.

It may be queſtioned whether a medium, capable of producing the effects of gravitation in this manner, would alſo be equally ſuſceptible of thoſe modifications which have been ſuppoſed neceſſary to the tranſmiſſion of light. In either caſe, it muſt be ſuppoſed to paſs through the apparent ſubſtance of all material bodies with the moſt perfect freedom, and there would, therefore, be no occaſion to apprehend any difficulty from a retardation of the celeſtial motion; the ultimate impenetrable particles of matter being, perhaps, ſcattered as thinly through its external form as ſtars are ſcattered in a nebula, which has ſtill the diſtant appearance of an uniform light; and there ſeems no reaſon to doubt the poſſibility of the propagation of an undulation through the Newtonian medium, with the actual velocity of light. It muſt be remembered, that the difference of its preſſure is not to be eſtimated from the actual bulk of the earth, or any other planet alone, but from the effect of the ſphere of repulſion of which that planet is the centre; and we may thus deduce the force of gravitation from a medium of no very enormous elaſticity.

Dr. Young obſerves, that a ſimilar combination of a ſimple preſſure with a variable repulſion is alſo obſervable in the force of coheſion, and ſuppoſes that if two particles of matter, floating in ſuch an elaſtic medium, capable of producing gravitation, were to approach each other, their mutual attraction would at once be changed from gravitation to coheſion, upon the excluſion of the portion of the medium intervening between them. The well known experiment of the two exhauſted hemiſpheres of Magdeburg affords an illuſtration of this hypotheſis, where we ſee apparent coheſion derived from atmoſpherical preſſure, and if we place between them a thick ring of elaſtic gum, we may repreſent the natural equilibrium between the forces of coheſion and repulſion, for the ring would reſiſt any ſmall additional preſſure with the ſame force as would be required for ſeparating the hemiſpheres ſo far as to allow it to expand in an equal degree; and at a certain point the ring would expand no more; the air would be admitted and the coheſion deſtroyed, as when a ſolid of any kind is torn aſunder. Theſe ſuppoſitions, however, are directly oppoſite to the hypotheſis which aſſigns to the elaſtic medium the power of paſſing freely through all the interſtices of the ultimate atoms of matter, ſince it could never paſs between two atoms cohering in this manner; we cannot, therefore, at preſent aſſert the identity of the forces gravitation and coheſion ſo ſtrongly as theory would allow us to do if eſtabliſhed. In ſhort, the whole of our enquiries reſpecting the intimate nature of forces muſt be conſidered as merely ſpeculative amuſements, which are of no farther utility than as they make our views more general, and aſſiſt our experimental inveſtigations.

La Place, after having ſhewn how the law of gravitation is deduced from the phenomena of the ſolar ſyſtem, concludes his reflections on this ſubject by enquiring whether the principle of gravitation is a primordial law of nature, or if it may not be the general effect of ſome unknown cauſe? Here, he obſerves, we are ſtopped by our ignorance of the nature of the intimate properties of matter, and deprived of every hope of anſwering this queſtion in a ſatisfactory manner. Inſtead, ſays this great author, of forming hypotheſes on this ſubject, let us content ourſelves with examining more particularly the manner in which this principle has been employed by philoſophers.

They have admitted the five following ſuppoſitions:

1. That gravitation takes place between the moſt minute particles of bodies.
2. That it is proportional to the maſſes.
3. That it varies inverſely as the ſquare of the diſtance.
4. That it is tranſmitted inſtantaneouſly from one body to another.
5. And that it equally acts on bodies in a ſtate of repoſe, and on thoſe which by their motion in the direction of its action ſhould ſeem likely to avoid a part of its influence.

The firſt of theſe propoſitions is, as we have ſeen, a neceſſary reſult of the equality which exiſts between action and re-action, every particle of the earth attracting it as the particle itſelf is attracted; this ſuppoſition is confirmed by the meaſures of the degrees of the meridian, and by experiments on pendulums; for amidſt all the irregularities of the meaſured degrees, we may perceive the traces of a regular figure, which is conformable to the theory. The great influence that the compreſſion of Jupiter has upon the nodes and perigees of the orbits of its ſatellites, proves to us that the attraction of this planet is compoſed of the attractions of all its particles. The proportionality of the attractive force to the maſſes is demonſtrated in the earth by experiments on pendulums, the oſcillations of which are of the ſame length of whatever ſubſtance they are compoſed. It is proved in the celeſtial regions by the conſtant relation which exiſts between the ſquares of the periodic times of bodies revolving about a common focus, to the cubes of the greater axes of their orbits.

We have ſeen with what preciſion the almoſt abſolute ſtate of repoſe of the perihelia of the planetary orbits indicate that the force of gravity varies according to the inverſe ſquare of the diſtance: and now that we know the cauſe of the motions of theſe perihelia, we may regard this law as rigorouſly exact. It is the ſame with all emanations which proceed from a centre, ſuch as light; it ſeems as if all forces whoſe action could be perceived at ſenſible diſtances obeyed this law. It has lately been obſerved, that the attractions and repulſions of electricity and magnetiſm decreaſe in proportion to the ſquares of the diſtances. A remarkable property of this law is, that if the dimenſions of all the bodies of the univerſe, their mutual diſtances and velocities were to be augmented or diminiſhed proportionally, they would deſcribe curves entirely ſimilar to thoſe deſcribed at preſent, and their appearances would be entirely the ſame. For the forces which animate them being entirely the reſult of attractions proportional to the maſſes divided by the ſquares of the diſtances, they would be augmented and diminiſhed proportionally to the dimenſions of this imaginary univerſe. It may be remarked at the ſame time that this property can only belong to the law of nature. Thus the apparent motions are independent of its abſolute dimenſions, as they are likewiſe of the motions it may have in ſpace, and we can only obſerve and recognize relative phenomena.

It is this law which gives to ſpheres the property of attracting each other mutually, as if their whole maſſes were united at their reſpective centres. It terminates alſo the orbits and the figures of the celeſtial bodies by lines and ſurfaces of the ſecond order, at leaſt if we neglect their perturbations and ſuppoſe them fluid.

We have no method of meaſuring the length of time in which gravity is propagated, becauſe the action of the ſun having once reached the planets, it continues to act on them as if the attractive force was communicated inſtantaneouſly to the extremities of the ſyſtem. We cannot, therefore, aſcertain in how long a time it is tranſmitted to the earth, no more than we could meaſure the velocity of light, were it not for the aberration, and the eclipſes of Jupiter's ſatellites. But it is not the ſame with the ſmall difference that may exiſt in the action of gravity upon bodies according to the direction of their velocity.

M. de la Place has found by analyſis, that an acceleration ſhould reſult in the mean motions of the planets round the ſun, and in the mean motions of the ſatellites about their planets.

M. de la Place had aſſumed this method of explaining the ſecular equation of the moon, when he believed, with other geometricians, that it was inexplicable on the principle of univerſal gravitation. He found that if it aroſe from this cauſe, a velocity muſt be ſuppoſed to exiſt in the centre of the moon, in order to releaſe it entirely from its gravity towards the earth, at leaſt ſix million times greater than that of light: the true cauſe of this equation being now known, we are certain that the action of gravity is much greater than this. This force, therefore, acts with a velocity which we may conſider as infinite; and we may conclude, that the action of the ſun is tranſmitted in an indiviſible inſtant to the extremities of the planetary ſyſtem.

Do any other forces act on the heavenly bodies beſides their mutual attractions?

We are unacquainted with any, and we may affirm that their effect is totally inſenſible. We may likewiſe be certain that theſe bodies experience no ſenſible reſiſtance from the fluids through which they paſs, as light, the tails of comets, or the zodiacal light.

The attractive force diſappears between bodies of an inconſiderable magnitude, and re-appears in their elements under a variety of forms. The ſolidity of bodies, their cryſtallization, the refraction of light, the elevation and depreſſion of fluids in capillary tubes, and all chemical combinations, generally are the reſults of attractive forces, the knowledge of which forms the principal object of natural philoſophy.

Are theſe forces the ſame as that of the gravity obſerved in the celeſtial regions, and modified on the earth by the figures of the integrant particles? To admit this hypotheſis we muſt ſuppoſe much more ſpace empty than full in all bodies, ſo that the denſity of their particles muſt be incomparably greater than the mean denſity of their whole volume. A ſpherical particle of one hundred thouſandth of a foot in diameter ſhould have a denſity at leaſt ten thouſand million of times greater than the mean denſity of the earth, to exert at its ſurface an attraction equal to the terreſtrial gravity. But the attractive forces of bodies greatly ſurpaſs this gravity, ſince they inflect light, whoſe direction is not changed by the attraction of the earth. The denſity of theſe particles ſhould, therefore, be to that of ſubſtances in a ratio which the imagination would fear to admit, if their affinities depended on the law of univerſal gravitation. The ratio of the intervals which ſeparate the particles of bodies to their reſpective dimenſions, would be of the ſame order as in ſtars which form a nebula, which in this point of view may be conſidered as a great luminous body. There is no reaſon, however, which abſolutely forbids us to conſider all bodies in this manner. Many phenomena are favourable to the ſuppoſition, particularly the extreme facility with which light penetrates diaphanous ſubſtances in all directions. The affinities would then depend on the integrant particles, and we might, by the variety of theſe forms, explain all the variety of attractive forces, and reduce to one general law all the phenomena of aſtronomy and natural philoſophy. But the impoſſibility of aſcertaining theſe figures, renders this inveſtigation uſeleſs to the advancement of ſcience.

Some geometricians, to account for theſe affinities, have added to the laws of attraction, inverſely as the ſquares of the diſtances, new terms which are inſenſible at ſmall diſtances; but theſe terms would be the expreſſions of as many different forces, and beſides being complicated with the different figures of the particles, they would only complicate the explanation of the phenomena.

Amidſt theſe uncertainties the wiſeſt plan ſeems to be, to endeavour to determine by numerous experiments the laws of affinities; and to effect this, the moſt ſimple method appears to be, by comparing theſe forces with the repulſive force of heat, which may be itſelf compared with that of gravity. Some experiments already made with this view, afford us reaſon to hope, that one day theſe laws will be perfectly known, and that then, by the application of analyſis, the philoſophy of terreſtrial bodies may be brought to the ſame degree of perfection, which the diſcovery of univerſal gravitation has procured for aſtronomy.

GRAVITY, in *Hydroſtatics*. The laws of bodies gravitating in fluids, make the buſineſs of hydroſtatics.

Gravity is here divided into *abſolute* and *ſpecific*.

GRAVITY, *abſolute or true*, is the whole force wherewith the body tends downward.

GRAVITY, *Specific*, called alſo *relative, comparative,* and *apparent* gravity, is the exceſs of gravity in any body, above that of an equal quantity or bulk of another; and denotes that gravity, or weight, peculiar to each ſpecies, or kind of natural body; and whereby it is diſtinguiſhed from all other kinds.

In this ſenſe, a body is ſaid to be *ſpecifically heavier* than another, when under the ſame bulk it contains a greater weight than that other; and that other is ſaid to be *ſpecifically lighter* than the firſt. Thus, if there be two equal ſpheres, each a foot in diameter; the one wood, the other lead, ſince the leaden one is found heavier than the wooden one, it is ſaid to be *ſpecifically*, or in *ſpecie*, *heavier*: and the wooden one *ſpecifically lighter*.

This kind of gravity ſome call *relative*; in oppoſition to *abſolute* gravity, which increaſes in proportion to the quantity or maſs of the body.

GRAVITY, *laws of the ſpecific, and levity of bodies.*—I. If two bodies be equal in bulk, their ſpecific gravities are to each other as their abſolute gravities. Thus a body is ſaid to be twice as heavy, *ſpecifically*, as another, if it have twice its gravity under the ſame bulk.

Hence, the ſpecific gravities of equal bodies are as their denſities.

II. If two bodies, compared together, be of the ſame ſpecific gravity, their abſolute weights will be as their magnitudes or bulks.

III. The ſpecific gravities of bodies of the ſame weight are in the reciprocal ratio of their bulks. Hence the maſſes of two bodies of the ſame weight are in a reciprocal ratio of their bulks.

IV. The ſpecific gravities of two bodies are in a ratio compounded of the direct ratio of the abſolute gravities, and the reciprocal one of their bulks. Hence, again, the ſpecific gravities are as the denſities.

V. The abſolute gravities of two bodies will be in a compound ratio of their ſpecific gravities and their bulks.

VI. The bulks of two bodies will be in a compound ratio of their abſolute gravities directly, and their ſpecific gravities inverſely.

VII. A body ſpecifically heavier than a fluid, loſes ſo much of its weight therein as is equal to the weight of a quantity of the fluid of the ſame bulk.

For, ſuppoſe a cubic inch of lead immerged in water; a cubic inch of water will, thereby, be expelled from its place: but the weight of this water was ſuſtained by the reſiſtance of the ambient water. Therefore, ſuch a part of the weight of the leaden cube muſt be ſuſtained by the reſiſtance of the ambient water, as is equal to the weight of the water expelled. The gravity of the body immerged, therefore, muſt be diminiſhed by ſo much.

Hence, 1. Since a fluid, ſpecifically heavier, has a greater weight, in the ſame bulk, than a lighter; the ſame body will loſe a greater part of its weight in a fluid, ſpecifically heavier, than in a lighter: and therefore it weighs more in a lighter than a heavier.

2. Equal homogeneous bodies weighing equally in air, loſe their equilibrium if one of them be immerged in a heavier fluid; the other in a lighter.

3. Since the ſpecific gravities are as the abſolute gravities under the ſame bulk; the ſpecific gravity of the fluid will be to the gravity of the body immerged, as part of the weight loſt by the ſolid, to the whole weight.

4. Two ſolids, equal in bulk, loſe the ſame weight in the ſame fluid: but the weight of the ſpecifically heavier body is greater than that of the ſpecifically lighter; therefore, the ſpecifically lighter loſes a greater part of its weight than the ſpecifically heavier.

5. Since the bulks of bodies, equal in weight, are reciprocally as the ſpecific gravities; the ſpecifically lighter loſes more weight in the ſame fluid than the heavier; wherefore, if they be in equilibrio in one fluid, they will not be ſo in another; but the ſpecifically heavier will preponderate, and that the more, as the fluid is denſer.

6. The ſpecific gravities of fluids are as the weights loſt by the ſame ſolid immerged in the ſame.

VIII. *To find the ſpecific gravity of a fluid.*—On one arm of a balance ſuſpend a leaden globe; and to the other, faſten a weight, which is in equilibrium therewith in the air. Immerge the globe ſucceſſively in the ſeveral fluids, whoſe ſpecific gravities are to be determined, and obſerve the weight which balances it in each. Theſe ſeveral weights, ſubtracted, ſeverally, from the firſt weight, the remainders are the parts of the weight loſt in each fluid. Whence the ratio of the ſpecific gravity of the fluids is ſeen.

Hence, as the denſities are as the ſpecific gravities, we find the ratio of the denſities of the fluids at the ſame time.

This problem is of the utmoſt uſe: as by it the degree of purity or goodneſs of fluids is eaſily found; a thing not only of ſervice in natural philoſophy, but alſo in common life, and in the practice of phyſic. See HYDROMETER.

That the ſpecific gravity may be found the more accurately, the weight of the thread not immerged in the fluid is to be ſubtracted from the weight of the ſolid in air; and the force neceſſary to make the thread ſubſide (if it be ſpecifically lighter) is to be added to the weight loſt. But if the thread that ſuſtains the ſolid be heavier than the fluid, the weight of the thread in the air is to be ſubtracted from the weight of the ſolid in air; and the weight the thread loſes from the weight loſt in the fluid. Indeed, this precaution may be ſpared, if, in examining the ſpecific gravity of ſeveral fluids, care be taken that the ſame thread be immerged to the ſame depth in each.

IX. To determine the ratio which the ſpecific gravity of a fluid has to the ſpecific gravity of a ſolid that is ſpecifically heavier than the fluid,

Weigh any maſs of the ſolid in a fluid, and note the juſt weight therein: the ſpecific gravity of the fluid will be to that of the ſolid, as the part of the weight loſt by the ſolid to its whole weight.

X. The ſpecific gravities of equally heavy bodies are reciprocally as the quantities of weight loſt in the ſame fluid. Hence we find the ratio of the ſpecific gravities of ſolids, by weighing maſſes thereof, that are equal in air, in the ſame fluid; and noting the weights loſt by each.

XI. A body, ſpecifically heavier, deſcends in a fluid ſpecifically lighter, with a force equal to the exceſs of its weight, above that of an equal quantity of the fluid.

Hence, 1. The force which ſuſtains a ſpecifically heavier body in a fluid, is equal to the exceſs of the abſolute gravity of the body, above that of the fluid, under the ſame bulk: *e. gr.* $47\frac{1}{3}$ pound of copper loſes $5\frac{1}{3}$ pounds of its weight in water; therefore a power of 42 pounds is able to ſuſtain it.

2. Since the exceſs of the weight of a ſolid over the weight of a fluid ſpecifically heavier, is leſs than that over the weight of a ſpecifically lighter fluid under the ſame bulk; it will deſcend with leſs force in a ſpecifically heavier fluid than in a lighter; and, conſequently, it will deſcend more ſlowly in the former than in the latter.

XII. A ſpecifically lighter body ſinks in a heavier fluid, till the weight of a quantity of the fluid, equal in bulk to the part immerſed, be equal to the weight of the whole body.

Hence, 1. Since the ſpecific gravities of bodies of the ſame weight are reciprocally as their bulks; and the bulks of fluids equal in weight, are as the parts of the ſame ſolid immerged therein; the ſpecific gravities of fluids are reciprocally as the parts of the ſame body immerged therein.

2. A ſolid, therefore, immerges deeper in a lighter fluid than in a heavier, and deeper, as the proportion of the ſpecific gravity of the ſolid to that of the fluid is greater.

3. If a body be of the ſame ſpecific gravity with a fluid,

the whole body will be immerged; and it will remain in any given place of the fluid.

4. If a ſpecifically lighter body be wholly immerged in a fluid, it will be urged, by the collateral columns of the fluid, to aſcend with a force equal to the exceſs of the weight of the fluid, bulk for bulk, over the weight of the ſolid.

5. A body, therefore, ſpecifically lighter, lying on the bottom of a veſſel, will not be raiſed up, unleſs the heavier fluid riſe above ſuch a part as is equal in bulk to a quantity of the fluid of the ſame weight with the whole ſolid.

XIII. The ſpecific gravity of a ſolid is to the ſpecific gravity of a lighter fluid, wherein it is immerged, as the bulk of the part immerged is to the whole bulk.

XIV. The ſpecific gravities of equal ſolids are as their parts immerged in the ſame fluid.

XV. The weight and bulk of a ſpecifically lighter body, and the weight of the ſpecifically heavier fluid, being given, to find the force required, to keep the ſolid wholly immerged under the fluid.

As this force is equal to the exceſs of the weight of the fluid beyond that of an equal bulk of the ſolid; from the given bulk of the ſolid, and the weight of a cubic foot of water, find, by the rule of three, the weight of a bulk of water equal to that of the body. From this ſubtract the weight of the ſolid; the remainder is the force required. *E. gr.* Suppoſe the force neceſſary to detain a ſolid eight feet in bulk, and 100 pounds in weight, under water, required: ſince a cubic foot of water is found to weigh 70 pound, the weight of water under the bulk of eight feet, is 560; whence, 100 pound, the weight of the ſolid, being ſubtracted; the remainder 460 pound is the force neceſſary to detain the ſolid under water.

Hence, ſince a ſpecifically lighter body aſcends in a heavier fluid, with the ſame force that would prevent its aſcent: by the preſent problem, we can likewiſe find the force wherewith a ſpecifically lighter body aſcends in a heavier.

XVI. The weight of a veſſel, to be made of a ſpecifically heavier matter; and that of a ſpecifically lighter fluid, being given: to determine the cavity the veſſel muſt have to ſwim on the fluid.

The weight of a cubic foot of the fluid being given, the bulk of the fluid equal to the weight of the veſſel is found by the rule of three. If, then, the cavity be made a little bigger than this, the veſſel will have leſs weight under the ſame bulk than the fluid, and will therefore be ſpecifically lighter than the ſame, and conſequently it will ſwim.

XVII. The force employed to retain a ſpecifically lighter ſolid, under a heavier fluid; and the weight loſt by a heavier ſolid in a lighter fluid, are each added to the weight of the fluid, and weigh together with it.

The ſeveral theorems here delivered, are not only all demonſtrable from the principles of mechanics, but are conformable to experiment. In effect, experience is here found to anſwer exactly to calculation, as is abundantly evident from the courſes of philoſophical experiments, now frequently exhibited; where the laws of ſpecific gravitation are well illuſtrated. See HYDROSTATICAL *balance*.

The ſpecific gravity of any ſubſtance is the relative weight of a given volume of it, compared with the ſame volume of ſome other ſubſtance taken as a ſtandard, and which is uſually diſtilled water at ſome given temperature. The abſolute gravity of a body is its entire weight, its ſpecific gravity is the weight of a given portion, as a cubic foot or cubic inch. As it would be very difficult, and in many caſes impoſſible, to meaſure the exact volume required to be weighed, a method of determining the ſpecific gravity of ſolids has been deviſed, founded on a principle of *Hydroſtatics*. It appears to have been known to Archimedes; that when a ſolid body, heavier than water, is plunged into that fluid, it loſes as much of its weight as is equal to the weight of the fluid it has diſplaced.

By the application of this principle we are enabled, in a very eaſy manner, to determine the ſpecific gravity of a body by firſt weighing it in air and afterwards in water. Then if the weight in air be divided by the weight loſt, or the difference of the weights in water and air, the quotient will expreſs the ſpecific gravity of that body, or the relative weight of an equal volume of that ſubſtance, and of the water in which the experiment was made.

The ſpecific gravity of two fluids may be determined by the ſame principle; for if we weigh a ſolid of any magnitude, as a ball of glaſs, firſt in water and then in any other fluid, the quantities of weight loſt in each experiment will be in the ſame proportion as the ſpecific gravity of the two fluids.

The ſpecific gravities of any ſubſtances, and in particular of ſuch as are lighter than water, may alſo be very conveniently determined by means of a common balance, employing a phial with a conical ground ſtopple filling it firſt with water and then either with a given fluid, or with a portion of the ſolid of which the weight has been aſcertained, together with as much water as is ſufficient to exclude the air.

It is neceſſary to attend to a great number of minute circumſtances when we wiſh to determine the ſpecific gravities of ſubſtances to a great degree of accuracy: theſe will be particularly noticed when deſcribing the particular inſtruments that have been invented for the purpoſe. See HYDROSTATIC *Balance*, HYDROMETER, &c.

One mode of aſcertaining the ſpecific gravities of fluids, differing but little from each other in denſity, is to have a ſeries of globules of glaſs ſo loaded, as to correſpond to the ſpecific gravities indicated by as many numbers, which are marked on them, and throwing ſeveral of them together into the fluid, and to obſerve which of them remains nearly ſtationary, without either riſing to the ſurface or ſinking. This method, though not expeditious, appears to be very ſecure from error, and is well adapted to determine the ſtrength of ſpirituous liquors. But in all theſe experiments it is neceſſary to be aware that a conſiderable change of the joint bulk of two ſubſtances is often produced by their mixture, and that in general their dimenſions are conſiderably contracted. Thus, 18 gallons of water and 18 gallons of alcohol, inſtead of 36 gallons, make only 35, conſequently the ſpecific gravity of the compound is one 35th greater than the mean of the ſpecific gravities of the ingredients. And in ſome caſes the whole dimenſion of a ſingle ſubſtance may even be contracted by the addition of another ſubſtance; thus iron, by the addition of one-eighth of its bulk of platina, becomes contracted one-fortieth of that bulk.

For meaſuring the ſpecific gravity of gaſſes, Mr. Leſlie has deviſed a new method, which conſiſts in obſerving the time employed in emptying a veſſel through a ſmall orifice, by means of the preſſure of an equal column of water.

A Table of Specific Gravities.

Principally from Davies and Lavoiſier. Davies's table is compiled with great diligence from many different authors; Lavoiſier's is chiefly extracted from Briſſon; it is carried to four places of decimals, but little dependence can be placed on the laſt.

GRAVITY, in *Mechanics*, denotes the conatus or tendency of bodies towards the centre of the earth.

That part of mechanics which conſiders the motion of bodies ariſing from gravity, is peculiarly called *ſtatics*.

Gravity, in this view, is diſtinguiſhed into *abſolute*, and *relative*.

The former is that with which a body deſcends freely through an unreſiſting medium: the laws of which ſee under DESCENT *of bodies*, ACCELERATION, MOTION, *Inclined* PLANE, &c.

The latter is that with which a body deſcends after having ſpent part of its weight in overcoming ſome reſiſtance. Such is that with which a body deſcends along an inclined plane, where ſome part is employed in overcoming the reſiſtance, or friction of the plane. The laws of relative gravity, ſee under *inclined* PLANE, DESCENT, FLUID, RESISTANCE, &c.

GRAVITY, *Centre of.* See CENTER *of gravity*.

GRAVITY, *Diameter of.* See DIAMETER *of gravity*.

GRAVITY, *Paracentric ſolicitation of.* See PARACENTRIC.

GRAVITY, *Plane of.* See PLANE *of gravity*.

GRAVITY, *Retardation from.* See RETARDATION.

GRAVITY *of the air.* See WEIGHT *of the Air*, AIR and ATMOSPHERE.

GRAVITY, in *Muſic*, is an affection of ſound by which it becomes denominated *grave*, low, or flat.

Gravity ſtands in oppoſition to *acuteneſs*, which is that affection of ſound by which it is denominated *acute*, *ſharp*, or *high*.

The relation of gravity and acuteneſs, is the principal property on which muſic depends; and it is the diſtinct, fixed, and determinate quality of this relation which entitles ſound to the denomination of *melodious*, *harmonical*, or *muſical*.

Gravity is, therefore, that modification of ſound by which it is conſidered as *grave* or low, with reſpect to, or compared with, other ſounds, that are acute or high. See ACUTE.

The degrees of gravity, &c. depend on the nature of the ſonorous body itſelf, and the particular figure and quantity thereof: though, in ſome caſes, they likewiſe depend on the part of the body where it is ſtruck. Thus, *e. gr.* the ſounds of two bells of different metals, and the ſame ſhape and dimenſions, being ſtruck in the ſame place, will differ as to acuteneſs and gravity; and two bells of the ſame metal will differ in acuteneſs, if they differ in ſhape or magnitude, or be ſtruck in different parts.

So in chords, all other things being equal, if they differ either in matter, or dimenſion, or tenſion, they will alſo differ in gravity.

Thus again, the ſound of a piece of gold is much graver than that of a piece of ſilver of the ſame ſhape and dimenſions; and in this caſe the tones are, *cæteris paribus*, proportional to the ſpecific gravities: ſo a ſolid ſphere of braſs, two feet in diameter, will ſound graver than another of one foot diameter; and here the tones are proportional to the quantities of matter, or the abſolute weights.

But it muſt be obſerved, that acuteneſs and gravity, as alſo loudneſs and lowneſs, are but relative things. We commonly call a ſound *acute* and loud, in reſpect to another which is *grave*, or low with reſpect to the former; ſo that the ſame ſound may be both *grave* and *acute*, and alſo loud and low, in different compariſons.

The degrees of acuteneſs and gravity make the different tones or tunes, of voice, or ſound; ſo we ſay one ſound is in tune with another, when they are in the ſame degree of gravity.

The immediate cauſe or means of this diverſity of tones lies very deep. Mathematicians expreſs the proportion of ſound to ſound, by the ratio of numbers. The moderns fix it on the different velocity of the vibrations of the ſonorous body: in which ſenſe gravity may be defined, a relative property of ſound, which, with reſpect to ſome other, is the effect of a leſſer number of vibrations accompliſhed in the ſame time, or of vibrations of a longer duration. In which ſenſe alſo, acuteneſs is the effect of a greater number of vibrations, or vibrations of a ſhorter duration.

If the vibrations be iſochronous, the ſound is called muſical, and is ſaid to continue at the ſame pitch. See CHORD and STRING, in *Muſic*.

If two or more ſounds be compared in the relation of gravity, &c. they are either *equal*, or *unequal*, in the degree of tune. Such as are *equal*, or produced by iſochronous vibrations, are called *uniſons*.

The *unequal* including, as it were, a diſtance between each other, conſtitute that we call an interval in muſic; which is properly the difference, in point of gravity, between two ſounds.

Upon this inequality, or difference, does the whole effect depend; and in reſpect of this it is, that theſe intervals are divided into *concords* and *diſcords*. See HARMONICS and RATIO.

As the gravity of ſounds depends on the thickneſs, length, and tenſion, of the ſtrings, or on the length and diameter of the pipes, and, in general, on the volume or maſs of the ſonorous bodies; the increaſe of any of theſe qualities (except tenſion) augments the gravity of ſound. But there is no abſolute point of gravity in nature, and no ſound is *grave* or acute, but by compariſon.

GRAULKET, in *Geography*, a town of France, in the department of the Tarn, and chief place of a canton, in the diſtrict of Lavaur; nine miles N. E. of Lavaur. The place contains 3419, and the canton 7159 inhabitants, on a territory of 135 kilometres, in ſix communes.

GRAUN, CHARLES HENRY, in *Biography*, chapel-maſter to Frederic II. the late king of Pruſſia, was the favourite compoſer of that prince, from 1732 to the time of his deceaſe, in 1759. On the acceſſion of the prince of Pruſſia to the throne in 1740, his majeſty, having determined to have an Italian lyric theatre in his capital, ſent Graun to Italy to ſtudy the Italian language and taſte in muſic, and to engage vocal performers. Graun remained two years in Italy, during which time the king, his royal maſter, had conſtructed, in ſpite of the Sileſian war, one of the moſt magnificent, complete, and convenient theatres in Europe, for which Graun was the compoſer to the end of his life; and even after his deceaſe little muſic but of his compoſition was ever performed in it for a long time.

The works of this maſter are very numerous; before his arrival at Berlin, he ſet three or four operas in the German language at Brunſwick, but the words were bad, and it is not fair to judge of his genius by thoſe early productions.

He compoſed for the Berlin theatre, in the ſpace of fourteen years, from 1742 to 1756, twenty-ſeven Italian operas;

and for the church; a *Te Deum*, and a *Paſſione*, beſides miſcellaneous productions of leſs importance, as odes and cantatas, with the overture and recitatives of the paſtoral opera of Galatea, of which his majeſty, Quantz, and Nichelman, ſet the ſongs.

On the deceaſe of this excellent compoſer, innumerable poems and panegyrics were written to his memory. Among the "Critical Letters concerning Muſic," publiſhed by M. Marpurg, there is an addreſs to M. Fried. Wilhelm Zachariä, the celebrated poet and muſician of Brunſwick, recommending the death of Graun to his muſe. No great ſtreſs can be laid on panegyrics; however, there are few of Graun's admirers, who are not ready to burn with fire and faggot all thoſe who dare to doubt of this author's veracity.

" Graun, the brighteſt ornament of the German muſe, the noble maſter of ſweet melody, is now no more! creator of his own taſte, he ſpoke not, but to our hearts; tender, ſoft, compaſſionate, elevated, pompous, and terrible, by turns;—he could force tears of admiration from us, at his pleaſure; an artiſt, who made no other uſe of art, than to imitate nature, in the moſt pleaſing and expreſſive manner; each ſtroke of his pencil was equally perfect, full of invention, and of new ideas, his genius was inexhauſtible. The model of ſacred muſic, and in the theatre inimitable! a man who commanded our affections, not only by his talents, but by his virtues, of friendſhip, probity, and patriotiſm; no man was ever ſo univerſally lamented by the whole nation, from the king, to the loweſt of his ſubjects." Kritiſche Briefe uber die Tonkunſt. I. Band. Berlin 1760.

Now, to reverſe the medal; it is denied, by the other party, that Graun was the creator of his own taſte, which is the taſte of Vinci; they deny, that he is ever pompous or terrible, but ſay, that an even tenor runs through all his works, which never reach the ſublime, though the tender and graceful are frequently found in them; they are equally unwilling to ſubſcribe to his great invention, or the originality of his ideas; and think that ſtill more perfect models of ſacred muſic may be found in the choruſſes of Handel, and the airs and duos of Pergoleſi and Jomelli: nor can they well comprehend, how that compoſer can be called *inimitable*, who is himſelf an *imitator*.

We have recently examined the ſcores of Graun's operas, and ſee no reaſon for changing the opinion which we formed 30 years ago. He was certainly a great maſter, elegant in his melodies, and correct and regular in his harmony; but if any one of his operas were now to be revived, it would be thought in want of variety and fire.

During the life of his great and illuſtrious patron, he was revered as much at Berlin as Handel in England; both great men, moſt aſſuredly; but much diſcrimination is neceſſary in drawing a paralĺel between them. Handel formed his ſtyle on the beſt models of the old ſchool, at the time of its greateſt perfection; ſuch as Cariſſimi, Colonna, Aleſſ. Scarlatti, Steffani and Corelli; Graun on that of the inventor of the new ſtyle, Vinci; who, though extremely and juſtly admired for the grace and elegance of his melodies, the ſimplicity of his accompaniment, and the facility and clearneſs of his ſtyle in general, has been far ſurpaſſed by Pergoleſi, Jomelli, Piccini, Sacchini, and Paeſiello. Germany is perhaps more obliged to Graun for ſmoothing, ſimplifying, and poliſhing the rough, laboured, and inelegant ſtyle of their old maſters, than to any Italians that have been employed at the imperial court or at Dreſden, to ſet the dramas of Apoſtolo Zeno and Metaſtaſio. Handel had more ſpirit and invention, and Graun more poliſh and refinement. Handel was wholly unrivalled in the country where he ſpent the greateſt part of his life; but Graun had a rival in the Roman Catholic courts, in the celebrated Haſſe, his countryman, whoſe compoſitions were as much in circulation and favour all over Europe, as thoſe of Vinci and Pergoleſi. Thoſe of Graun ſeem wholly confined to Germany, and almoſt to the court of Berlin; nor do we ever remember to have heard Mara ſing one of his airs in England, though during many years ſhe performed the principal female parts in his operas at Berlin. His *Te Deum* was firſt appointed to be performed at the concert of ancient muſic in 1786, by the late duke of Leeds, then marquis of Caermarthen, and it has continued a ſtock piece ever ſince. Many of his duets, and his Tod Jeſu are admirable compoſitions, and he certainly deſerves to be ranked very high among the great maſters of the laſt century.

GRAUN, JOHN GOTTLIB, brother of the above compoſer, and concert-maſter to his late Pruſſian majeſty, Frederick II. his admirers at Berlin, ſay that " he was one of the greateſt performers on the violin of his time, and moſt aſſuredly, a compoſer of the firſt rank; his overtures and ſymphonies are majeſtic, and his concertos are maſter-pieces, particularly thoſe for two violins, in which he has united the moſt agreeable melody with all the learning that the art of counterpoint can boaſt; he has likewiſe frequently ſet the *Salve Regina*, and compoſed maſſes, which are rendered grand and noble by ſimplicity and good melody, even in the moſt laboured parts."

But leſs quarter is granted to this maſter, by the admirers of more modern muſic, than to his brother; they often find his overtures and ſymphonies too like thoſe of Lulli, and too full of notes to produce any other effect, when played at Berlin, than that of ſtunning the hearers: and in his concertos and church muſic, when that is not the caſe, the length of each movement is more immoderate, than Chriſtian patience can endure.

Perhaps the truth may lie between theſe two opinions; and with reſpect to the chapel-maſter Graun, it ſhould be remembered, that he was ſeldom allowed to follow the bent of his own genius.

GRAUNT, JOHN, born April 24, 1620, was brought up to the trade of a haberdaſher, but by his good ſenſe and integrity in buſineſs he acquired the eſteem of his fellow citizens, ſo as to be elected into the common council of the city of London. The bills of mortality, which were annually laid before this body, led Mr. Graunt to turn his attention to the ſcience of political arithmetic. From very ſmall beginnings he collected a large body of materials, from which he compoſed a work entitled " Natural and Political Obſervations made upon the Bills of Mortality." This work was well received by the public, and paſſed through ſeveral editions: it obtained likewiſe for the author an admiſſion into the Royal Society, upon the particular recommendation of the king, who gave it in particular charge to thoſe concerned, that if they found any more ſuch tradeſmen, they ſhould be ſure to admit them all. It is generally ſuppoſed that Mr. Graunt received valuable aſſiſtance from ſir W. Petty; but the ſtyle is ſuch as might be expected from a plain citizen, and the tabular form, preſenting at one view the general reſults of a number of important facts, was a thought eſſentially leading to all the concluſions which have ſince been eſtabliſhed relative to theſe ſubjects. After he retired from buſineſs, he was admitted a truſtee for ſir William Backhouſe, into the management of the New River Company, which, with the unlucky circumſtance of his being a convert to popery, gave occaſion to the groundleſs calumny of his having had a hand in the great fire of London.

The ſtory, though given by Burnet, is abundantly refuted by the writers of the Biographia Britannica. Mr. Graunt continued his application to his ſtudies, and made large additions to his "Obſervations" but two years before his death, which happened on the 18th of April, 1674. He was buried at St. Dunſtan's Weſt, and many of the moſt eminent and ingenious perſons of that time, among whom was ſir William Petty, paid their laſt reſpects to his memory. He left behind him a diſcourſe upon the advance of the exciſe, and ſome papers on religious topics, which have not been publiſhed. It muſt be mentioned to his honour, that immediately after the publication of his book, Lewis XIV. or his miniſters, enacted a law to enforce the moſt exact regiſter of births and burials that was to be found any where in Europe. Biog. Brit.

GRAUPEN, a term uſed by the German miners to expreſs the reſiduum of any ore after the regulus, or metalline part, is run from it. Thus the ores of biſmuth leave behind them, after the regulus is melted off, an earthy ſubſtance, called biſmuth graupen, with which, mixed with flints and an alkali, they make a kind of ſmalt, not diſtinguiſhable from the true ſmalt made from cobalt. Phil. Tranſ. N° 390.

GRAY, THOMAS, in *Biography*, a diſtinguiſhed Engliſh poet, deſcended from very reſpectable citizens of London, was born in Cornhill, December the 26th, 1716. His grandfather was a conſiderable merchant; but his father, Mr. Philip Gray, was of an indolent and reſerved temper; and therefore diminiſhed rather than increaſed his paternal fortune. He had many children, of whom Thomas, the ſubject of theſe memoirs, was the fifth: all of them except himſelf died in their infancy, and he is ſaid to have narrowly eſcaped ſuffocation, owing to a too great fullneſs of blood, which deſtroyed the reſt, and he would certainly have been cut off as early, had not his mother, with a courage remarkable for one of her ſex, ventured to open a vein with her own hand, which inſtantly removed the paroxyſm. He was probably deſtined for a profeſſion, and accordingly ſent to Eton ſchool to acquire the fundamental ſtock of claſſical literature. Here he was placed under the immediate care of Mr. Antrobus, his mother's brother, at that time one of the aſſiſtant maſters, and likewiſe a fellow of St Peter's college, Cambridge, to which place Mr. Gray removed, and was admitted a penſioner in the year 1734. Of his reſidence at Cambridge few memorials are recorded; he ſeems rather to have cultivated a literary taſte in ſilence, than to have had any aim at public diſtinction. He nevertheleſs appeared as a poet among the univerſity congratulators of the prince of Wales's marriage, and his verſes were admitted to be the beſt of the academical collection. His letters, during this period, to Mr. Weſt, which are printed by Mr. Maſon, ſhew that he had little reverence for the graver ſtudies, or for the dignified perſonages of the place, and that he had acquired that claſſic faſtidiouſneſs which was the permanent feature in his character. He quitted college in 1738, and occupied a ſet of chambers in the Inner Temple, with the avowed intention of ſtudying the law. A Latin ode, addreſſed upon this occaſion to Mr. Weſt, who had the ſame purpoſe in view, exhibits in a ſtriking manner the aſcendancy which the poet poſſeſſed in his mind over the ideal lawyer; and on the invitation which Mr. Walpole gave him to be the companion of his travels, he laid aſide this intention, and never after reſumed it. They ſet out in the ſpring, and his letters from the different ſtages of his progreſs, are a proof of the intelligent curioſity with which he viewed all the ſtriking objects of art and nature, and the manners and habits of mankind. Thus, in his letter from Amiens, he deſcribes every thing that he ſaw on the road, paints in vivid colours what was remarkable in the ſeveral towns through which he paſſed; and he adds, that "on every hillock is a windmill, a crucifix, or a Virgin Mary dreſſed in flowers, and a ſarſenet robe; one ſees not many people or carriages on the road; now and then a ſtrolling friar, a countryman with a great muff, or a woman riding aſtride on a little aſs, with ſhort petticoats, and a great head-dreſs of blue wool." They travelled through France, croſſed the Alps, viſited the principal towns of Italy as far as Naples, returned to Florence, and in the ſpring of 1741 proceeded for Venice. Upon their way thither the two companions fell into a diſagreement, which occaſioned their ſeparation Of this unfortunate incident the biographer ſays, "Mr. Walpole enjoins me to charge himſelf with the chief blame in their quarrel; confeſſing that more attention and complaiſance, more deference to a warm friendſhip, ſuperior judgment and prudence, might have prevented a rupture that gave much uneaſineſs to them both, and a laſting concern to the ſurvivor; though, in the year 1744, a reconciliation was effected between them." Mr. Gray, with his own very moderate reſources, finiſhed the reſt of the tour, and arrived in England in September 1741, two months previouſly to the death of his father. He now returned to academic retirement at Cambridge. In the following year he had the misfortune to loſe his friend Mr. Weſt, the confident of his ſentiments and partner of his ſtudies. The death of this hopeful young man left a vacancy in Mr. Gray's heart, which was never after ſupplied. He had an ambition to excel in Latin poetry, but was convinced that laſting fame could only be acquired by works accordant to the general taſte of his countrymen. He made many noble beginnings of poems, which, if he had poſſeſſed perſeverance enough to have completed them, would have redounded to his immortal honour. In the year 1742, he took the degree of bachelor of civil law, a circumſtance which gave him every neceſſary privilege for improving an univerſity reſidence, and he ſat down to a courſe of reading, which he purſued with the diligence of an exact critic. For ſeveral years his exquiſite learning and high poetic talents were known to but a very few of his moſt intimate friends. In 1747 he publiſhed his "Ode on the diſtant Proſpect of Eton College;" and in 1751 his "Elegy written in a Country Church-yard," was ſent into the world without the author's name. Few poems were ever ſo popular; it has paſſed through an almoſt indefinite number of editions, and is at this moment one of the moſt favourite productions of the Britiſh muſe. It has been tranſlated into Latin and Greek verſe. In 1753 Gray buried his mother, to whom he had always behaved with true filial duty and affection, and on her tomb he wrote, "the tender mother of many children, one of whom alone had the misfortune to ſurvive her." At college he was, on account of ſome peculiarity in his manners, ſubject to the boiſterous tricks of a few riotous young men of fortune, who took a pleaſure in diſturbing and alarming him; he made remonſtrances on the ſubject to the heads of the houſe, which not producing the effect which he anticipated, he removed his reſidence to Pembroke Hall in 1756, and in the ſucceeding year he was, on the death of Cibber, offered the poſt of poet laureat, which he declined. His motive for refuſing this office could not have been through any doubt of his being adequate to its duties, for in the ſame year he ſhewed what he was capable of doing as a lyric poet by the publication of his two principal odes, entitled "On the Progreſs of Poeſy;" and "The Bard." It would indeed have been moſt lamentable that a man of his genius and independent mind ſhould have been fettered by the obligation of producing periodical oblations of court incenſe. The odes juſt mentioned were much leſs popular than the elegy: many could not underſtand them, ſome ridiculed them, and in general they were more the objects of aſtoniſhment than of rapturous feeling; nevertheleſs, among perſons of real literary taſte, they raiſed the author's poetical character to a level with that of the firſt poets of his country. In the year 1759, Mr. Gray varied the uniformity of his life by a reſidence, which continued three years, in lodgings near the Britiſh Muſeum, chiefly for the purpoſe of conſulting curious books and manuſcripts in that great national repoſitory. In 1765 he took a journey into Scotland for his health, was introduced to the moſt eminent literati in that country, and fed his imagination with thoſe ſcenes of natural ſublimity and beauty which no man was better qualified to taſte, and to improve. He had, previouſly to this, ſought for the profeſſorſhip of modern hiſtory at Cambridge, but either his application was too late, or the patron, lord Bute, had other intereſts to ſerve; it was given to another candidate. A ſecond vacancy occurred in 1768, when it was conferred upon him, unſolicited and unexpected, in the moſt handſome way poſſible, by the duke of Grafton, who, notwithſtanding ſome defects in the former part of his life, has always been capable of doing noble things in a noble manner. The place was worth 400*l. per ann.* and Gray made a voluntary return for the favour by an "Ode to Muſic," for the inſtallation of that nobleman, as chancellor of the univerſity in 1769. His new office laid him under an obligation to ſome exertions: he might indeed have ſheltered himſelf by the example of his predeceſſors, and received the emoluments without paying any regard to its duties, but the idea of retaining a perfect ſinecure did not accord with his temper; he immediately ſet about preparing for active ſervice, he ſketched an admirable plan for his inauguration ſpeech, in which, after enumerating the preparatory and auxiliary ſtudies requiſite, as ancient hiſtory, geography, chronology, &c. he deſcended to the authentic ſources of the ſcience, ſuch as public treaties; ſtate records, private correſpondence of ambaſſadors, &c. He alſo drew up and laid before the duke of Grafton, three different ſchemes for regulating the method of chooſing pupils privately to be inſtructed by him, which were highly approved, and if he had been accuſtomed, by general habits, to thoſe exerciſes which he felt would have been beneficial to the improvement of his pupils, much might have been expected from his lectures, but with a mind replete with the ſtores of knowledge, ancient and modern, he was totally unable, through the baneful effects of habitual literary indolence, to bring his vaſt acquiſitions to uſe on demand; and after many uneaſy ſtruggles, he proceeded no farther than to ſketch out a plan. His health was indeed rapidly on the decline; low ſpirits, "the indolent ſcholar's familiar malady," ſeized him; an irregular hereditary gout made more frequent attacks than uſual on his feeble conſtitution: at length a ſudden nauſea, with which he was affected while dining in the College Hall, announced that the diſeaſe had left the extremities and attached itſelf in the ſtomach. He died July 30th 1771, in the fifty-fifth year of his age. He was ſenſible to the laſt, and aware, through the whole of the diſeaſe, of his great danger, but expreſſed no viſible concern at the thoughts of his approaching diſſolution. With a warm imagination, Mr. Gray had cool affections, and a calm ſedate diſpoſition. He was attentive from economy, yet wholly void of avarice: he was generous, even when his circumſtances were the moſt narrow. He was careful of himſelf, and ſo timorous, that it is aſſerted, ſome of the fineſt views in a tour to the Lakes eſcaped him, becauſe he did not chooſe to venture to thoſe ſpots whence they were to be ſeen. This want of perſonal courage is a ſingular contraſt with the manly and martial ſtrains of his poetry. In morals he was temperate, upright, and a conſtant friend to virtue. His religious opinions were not known, but he always abhorred the diſſemination of ſcepticiſm and infidelity. Few men of his reputation have had leſs vanity, and he bore with good-humour and eaſy negligence all the criticiſms upon his compoſitions. The learning of our poet was general and deep: it comprifed almoſt every topic of human enquiry, excepting what belonged to the ſciences properly ſo called. As a poet his name muſt deſcend to the lateſt poſterity, at leaſt, as long as there is taſte enough left to feel and enjoy elegant writing. No one appears to have poſſeſſed more of that faculty of poetical perception which diſtinguiſhes among all the objects of art and nature what are fitteſt for the poet's uſe, together with the power of diſplaying them in their richeſt colours. According to a critic, Mr. Gray "did not excel in pure invention, neither is he highly pathetic or ſublime, but he is ſplendid, lofty, and energetic; generally correct, and richly harmonious. Though lyric poetry is that in which he has chiefly exerciſed himſelf, he was capable of varying his manner to ſuit any ſpecies of compoſition. Perhaps he was beſt of all qualified for the moral and didactic, if we may judge from his noble fragment of "An Eſſay on the Alliance of Education and Government." As a writer of Latin verſe he is perhaps ſurpaſſed by few in claſſic propriety. His letters are entertaining and inſtructive; free from all parade; they poſſeſs a fund of pleaſantry, which will ever render them popular among thoſe of his countrymen, who are at all imbued with the principles of literary taſte. By a friend who has deſcribed his character it is ſaid that "perhaps he was the moſt learned man in Europe; he was equally acquainted with the elegant and profound parts of ſcience, and that not ſuperficially but thoroughly. He knew every branch of hiſtory both natural and civil, and had read all the original hiſtorians of England, France, and Italy; and was a great antiquarian. Criticiſm, metaphyſics, morals, and politics, made a principal part of his plan of ſtudy; voyages and travels of all ſorts were his favourite amuſement, and he had a fine taſte in painting, prints, architecture, and gardening: with ſuch a fund of knowledge, his converſation muſt have been equally inſtructive and entertaining; but he was alſo a good man, a well bred man, a man of virtue and humanity. There is no character without ſome ſpeck, ſome imperfection; and I think the greateſt defect in his, was an affectation in delicacy, or rather effeminacy, and a viſible faſtidiouſneſs or contempt and diſdain of his inferiors in ſcience. He alſo had in ſome degree that weakneſs which diſguſted Voltaire ſo much in Mr. Congreve: though he ſeemed to value others chiefly according to the progreſs they had made in knowledge, yet he could not bear to be conſidered himſelf merely as a man of letters; and though without birth, or fortune, or ſtation, his deſire was to be looked upon as a private independent gentleman." Maſon's Life and Letters of Gray, four vols. 8vo. 1778.

Gray, or *Grey*, a mixed colour, partaking of the two extremes, black and white. In dyeing, many of the varieties of grey, iron-grey, ſlate colour, &c. are given by proceſſes, in general, ſimilar to thoſe for black, but with ſmaller quantities of the ingredients, and eſpecially a ſhorter time of immerſion. They are often finiſhed with a weak bath of weld, cochineal, Brazil-wood, and other livelier colours to give ſome particular tints.

In the *Manege* they make ſeveral ſorts of grays: as the *branded* or *blackened* gray, which has ſpots quite black, diſperſed here and there. The *dappled* gray, which has ſpots of a darker colour than the reſt of the body. The *light* or *ſilver* gray, wherein there is but a ſmall mixture of black hairs. The *ſad* or *iron* gray, which has but a ſmall mixture of white. And the *browniſh* or *ſandy-coloured* gray, where there are bay-coloured hairs mixed with the black.

GRAY, in *Zoology*, a name given in ſome counties of England to the badger.

GRAY is alſo uſed in ſome places for a ſpecies of wild-duck, more commonly known by the name of the *gadwall*. See DUCK.

GRAY, in *Geography*, a town of France, and principal place of a diſtrict, in the department of the Upper Saône, ſeated on the Saône, which is navigable by boats to Lyons, whither the inhabitants ſend grain and iron, the chief articles of their commerce. The place contains 5009, and the canton 13,825 inhabitants, on a territory of 215 kiliometres, in 26 communes. N. lat. 47° 27′. E. long. 53° 40′.

GRAY, a poſt-town of America, in Cumberland county and ſtate of Maine; 15 miles N.W. from Portland. The townſhip was incorporated in 1778, and contains 987 inhabitants.

GRAY's *Bay*, a bay on the N. ſide of the river Columbia, in New Georgia. N. lat. 46° 19′. W. long. 236 22′.

GRAY's *Creek*, a river of Virginia, which runs into James river. N. lat. 37° 8′. W. long. 76° 56′.

GRAY's *Harbour*, a port or bay on the W. coaſt of North America, examined and deſcribed by Mr. Whitbey. The ſurrounding ſhores are low and apparently ſwampy, with ſalt-marſhes; the ſoil is a thin mixture of red and white ſand over a bed of ſtones and pebbles. At a ſmall diſtance from the water ſide, the country is covered with wood, chiefly pines of an inferior ſtunted growth. The number of Indians inhabiting this place were eſtimated at about 100; they ſpoke the Nootka language, though it did not ſeem to be their native tongue, and they appeared to vary in little or no reſpect from thoſe people occaſionally ſeen. N. lat. 47°. E. long. 236° 7′.

GRAYLING, or UMBER, the Engliſh name for the fiſh called by authors *thymallus*, and *thymus*, and by Artedi made a ſpecies of corregonus, and the SALMO *thymallus* of Linnæus, which ſee.

It is caught in the freſh rivers and clear rapid ſtreams, chiefly in the mountainous counties of England, and in the like ſituations in Germany, and other kingdoms, and is one of the fineſt taſted of all the freſh-water fiſh. It is common in Lapland, where the guts of it are uſed inſtead of rennet to make cheeſe, which they get from the milk of the rein-deer. It is a voracious fiſh, riſes freely to the fly, and will very eagerly take a bait. It feeds on worms, and ſpawns in May.

GRAYSON, in *Geography*, a county of Virginia in the upper waters of the Great Kanhawa. It contains 3742 free inhabitants, and 170 ſlaves. Its form is triangular; the longeſt line being about 50 miles, and its greateſt breadth 15 miles. It is mountainous, abounding with timber and iron ore; and two ſets of iron-works are erected in it: about a fifth part is arable. The court houſe is in N. lat. 36° 35′, 250 miles S.W. of Richmond.

GRAZALEMA, a town of Spain, about 1½ mile from the borders of the province of Granada, built partly on the ſide, and partly on the top of a mountain. Moſt of the inhabitants are employed in the manufacture of woollen and coarſe cloths, and alſo of crucibles. Their number is about 5000.

GRAZIANI, ANTON-MARIA, in *Biography*, a biſhop and elegant writer, was born of a diſtinguiſhed family at Borgo-ſan-Sepolcro, in Tuſcany, about the year 1537. Having obtained a good knowledge of grammatical learning at Friuli under the celebrated Abſtemio, he was ſent to Padua to ſtudy the law. In 1560 he viſited Rome, and was kindly patronized by Commendone, afterwards cardinal. He accompanied this friend, between whom and himſelf there was an unalterable attachment, in all his journeys into Germany and Poland, and refuſed to quit him, though ſolicited with great promiſes by Henry of Valois, at that time king of the latter country. After the death of Commendone in 1584, he was made ſecretary to pope Sixtus V., and took a conſiderable ſhare in the election of Clement VIII. who, in 1592, in gratitude for his ſervices, created him biſhop of Amelia, and ſent him as his nuncio to the Italian princes and ſtates, in order to unite them in a league againſt the Turks. When at Venice, he prevented that republic from declaring in favour of Cæſar d'Eſte after the demiſe of Alphonſo II. duke of Ferrara. In 1598 he retired to his ſee, where he remained, till his death in 1611, moſt aſſiduouſly employed in the duties of his high office. As an author Graziani is known by the following works, "De Bello Cyprio," lib. v. 4to. 1624; "A Hiſtory of the War of Cyprus:" "De Vita Commendoni, Cardinalis," which was intended as a tribute of gratitude and affection to his deceaſed friend and patron: "De Caſibus adverſis Virorum illuſtrium," and a collection of ſynodal ordinances. In 1745 the public were preſented with a curious poſthumous work of this author, entitled "De Scriptis Invita Minerva, ad Aloyſium Fratrem," lib. xx. in which he not only gives an account of his own life and writings, but that of his native town and family; of his brother's travels, and of the public affairs in which he was engaged. Moreri.

GRAZIANI, D. BONIFACIO DA MARINO, maeſtro di capella of the Jeſuits' chapel and ſeminary at Rome, was a very voluminous compoſer of ſacred muſic and cantatas, who flouriſhed from the year 1650 to 1678. Padre Martini has given the following liſt of his eccleſiaſtical publications; three books of pſalms for five voices, *a due cori*, or for two choirs; publiſhed at Rome 1652 and 1670. Maſſes *à* 5 Rome, 1671. Six books of motets, for 1, 2, 3, 4, 5 and 6 voices; Rome, from 1651 to 1671; antiphons, for the bleſſed virgin Mary, for 4, 5 and 6 voices, Rome, 1665. *Reſponſ. della Settim. ſanta*, Rome, 1663. *Litanie* for 3, 4, 5, and 8 voices, Rome 1675. Sacred and moral compoſitions, for 1, 2, 3 and 4 voices, 1678. Of his cantatas, though none are mentioned in this liſt, yet the number of them, that have been preſerved in MS. collections of old muſic, is equal to thoſe of Cariſſimi, Ceſti, and Luigi Roſſi, particularly in the Britiſh Muſeum; Dr. Aldridge's collection of muſic in the library of Chriſt-church, Oxford; Dr. Burney's Collect. &c.

GRAZIER, in *Agriculture*, a term commonly applied to ſuch farmers as are engaged in the art and buſineſs of fattening various ſorts of live ſtock on paſture and other graſs-lands. That this ſort of buſineſs may be managed to the beſt poſſible advantage, the grazier ſhould have a perfect knowledge of the nature, properties, and value of all ſorts of cattle and ſheep ſtock, as well as of the quality of the ground on which they are to be fed, and of the moſt proper methods of ſuiting them to each other. And he ſhould alſo be well informed concerning the nature and ſtates of markets in general. It is obvious that upon theſe being well underſtood and properly regarded, much of the ſucceſs of this ſort of farming buſineſs muſt depend, as thereby proper advantage may be taken, not only of fairs and markets, but a variety of other neceſſary circumſtances.

The markets for the ſale of fat ſtock, eſpecially thoſe of the neat cattle and ſheep kinds, are generally as high about the end of April as at any other period of the year, in conſequence of the ſupply, at that ſeaſon of the year, being only had from cake or corn-fed animals, not one farmer in a thouſand having then any ſort of winter green food remaining. On this account ſuch beaſts or ſheep as are really fat at that time are ſure to fetch a good price in the markets, and particularly at Smithfield. With the latter animals, however, the caſe is, in ſome inſtances, rather different as to thoſe farmers who are good providers: ſpring food is now beginning to be ready, though ſeldom in ſuch plenty, from the number of bad managers, as to reduce the markets in any great degree.

The inexperienced grazier ſhould conſequently fully weigh and conſider the different modes in which he may be able to diſpoſe of his fat ſtock to the greateſt advantage. The firſt and principal place to which his attention will be directed, will probably be Smithfield market, eſpecially for the more ſouthern graziers. If he be ſituated in a diſtrict that is divided into ſmall or middling ſized farms, and in which the farmers are commonly in the regular practice of employing diſtrict drovers, in whom proper confidence can be placed, he will of neceſſity be as ſafe as his neighbours, and may not have reaſon for any particular caution. This mode is very common in the eaſtern part of the county of Norfolk. Where he occupies a very large farm, whatever the nature of it may be, whether an arable grazing one, as is cuſtomary in Weſt Norfolk, or a graſs grazing one, as in the county of Lincoln, on a ſcale that enables him to ſend many droves in a pretty regular manner to his ſaleſman, he may ſafely truſt to him; as the uſual confidence and integrity of trade moſtly take place in ſuch caſes. But it muſt be obſerved, that it is ſeldom the caſe that the grazier who ſends occaſionally or accidentally a lot of fat beaſts or ſheep to Smithfield market, gets as fair a price for them as his great neighbour, who is in conſtant dealing, gets the ſame day, or his little one, whoſe ſtock took the ſame chance through the means of a confidential drover. The perſon who thus drops in a lot, out of the regular courſe of his buſineſs, is ſcarcely ever ſatisfied with the treatment he meets. And there is, without doubt, much truth in the remark, in conſequence of the frequency of its being made by perſons from different places.

On this account the inexperienced grazier ſhould conſider the circumſtance well, and try the country butchers, in order to feel his way through the difficulty as well as he can, provided his farm be of ſuch a ſize, and in ſuch a ſituation, as to lay him open to its influence and effects.

In the buſineſs of grazing, great advantage may be derived, by thoſe who have not had much experience, from the frequent weighing of the animals while alive; as by a compariſon of the living with the dead weight, in ſuch caſes, as when they are killed in their own neighbourhoods, they may ſoon become able to judge, with a tolerable degree of correctneſs, of the dead weight of any common ſized beaſt, of which they have aſcertained the weight while in the living ſtate. And where the living weight has been taken from tables of admeaſurement, ſuch as thoſe compoſed by Bantor, they may compare the reſult in a pretty exact way.

The work of aſcertaining the living weight in ſheep, calves, hogs, and other ſimilar kinds of animals, may be effected in a ſimple and eaſy manner, merely by the contrivance of a ſort of cage or large covered baſket, with a door at each end for their reception and diſcharges, to which is attached a pair of large ſteelyards, ſo as to ſhew the weight.

The frequent weighing of the fattening ſtock ſhews the grazier the different degrees of progreſs which the animals have made in different periods and ſituations, as well as what the effects of different ſorts of food are upon them; what changes may be neceſſary in it, and when it may be the moſt proper to ſell, provided the markets ſhould be ſuitable. In ſhort, a ſort of confidence is in this way gained by the grazier, that could not be readily acquired in any other manner.

But aſſiſtance of this nature is not by any means neceſſary for ſuch graziers as have been long accuſtomed to the handling and judging of the weights of animals, as they can in general form tolerably correct opinions by the eye and the feel, in conſequence of ſuch long experience; though it not unfrequently happens that they are deceived, the beaſts turning much better and heavier than they had imagined. It has, indeed, been remarked that, let the grazier be as experienced as he may in buying and ſelling, as well as in judging by the hand and the eye, the butcher will beat him, from having been able to bring the live to the teſt of the dead weight, in ſuch a variety of different inſtances, as muſt render his judgment perfect. The grazier, though he cannot therefore equal him, may, in a great meaſure, approximate to him by means of frequent careful weighing of the living animals.

It muſt of courſe appear evident that it is a matter of great conſequence for the ſtock farmer, to make himſelf, as ſoon as poſſible, perfectly converſant with this part of his buſineſs, as without it he muſt be liable to be greatly deceived in his dealings.

GRAZING, the practice of feeding and paſturing down graſs-lands with different ſorts of live ſtock, with the intention of improving and rendering them fit for the market. It is a ſort of management that cannot be carried on to much advantage, except in thoſe diſtricts where the quantity of paſture land is conſiderable, and of a ſuitable quality for the purpoſe, or where the value of the produce of ſuch ſward land is but ſmall in compariſon with the ſtock which is fed upon it.

There are particular diſtricts in different parts of the kingdom that are much more in this ſyſtem of farming than others, as is exemplified by thoſe of the counties of Lincoln and Leiceſter, in the middle part of the iſland, Somerſet, Glouceſter, &c. in the weſt, and Romney marſh, &c. in the ſouth.

But there are tracts of grazing ground of more or leſs extent in moſt of the counties of the kingdom.

It is well remarked that there are certain ſituations as well as deſcriptions of paſture ground on which this method of farming may be had recourſe to with better profits, and more ſucceſs than that of any branch of the dairying ſyſtem. This muſt be the caſe in all thoſe diſtricts where the proportion of land in the ſtate of tillage is very ſmall in compariſon to that of the paſture kind, conſequently the price of produce of the graſs ſort trifling in compariſon to that of the fat ſtock. In all ſuch diſtricts of the kingdom where the graſs-lands are of ſo fine and rich a quality, as to be capable of fattening large bullocks or other cattle, this ſyſtem may be had recourſe to with much ſucceſs and profit, and is perhaps the beſt application to which the lands can be applied, as is fully ſhewn by ſuch diſtricts being moſtly under ſome management or other of this nature.

It may be obſerved that the art of grazing to advantage depends upon a variety of circumſtances, ſuch as thoſe of the nature and quality of the grounds, the propriety of the management of them in reſpect to feeding down, changing, and ſhutting them up; the properly adapting the ſtock to them in quantity, ſize, and quality; the judgment of the grazier not only in ſelecting ſuch as are moſt ſuitable for the purpoſe and moſt diſpoſed to fatten, but in obtaining them, where they are to be purchaſed, at ſuch prices as that they may pay well for keeping; and diſpoſing of them, when fattened, at their full value and advantage.

It has been ſtated, by Mr. Kent, that the ſtocking of land with proper cattle is one of the niceſt parts of the ſcience of farming. Where nature is left to herſelf, ſhe always produces animals ſuitable to her vegetation, from the ſmalleſt ſheep on the Welſh mountains to the largeſt ſort in the Lincolnſhire marſhes; from the little hardy bullock in the northern highlands to the noble ox in the richeſt paſtures in Somerſetſhire. But good huſbandry admits of our increaſing the value of the one in proportion to that of the other. Land improved enables us to keep a better ſort of ſtock, which ſhews the double return the earth makes for any judicious attention or labour we beſtow upon it. The true wiſdom of the occupier is beſt ſhewn in preſerving a due equilibrium between this improvement of his land and ſtock. They go hand in hand, and if he neglect the one, he cannot avail himſelf of the other. It ſhould, therefore, be firſt conſidered what kind of cattle, or other ſorts of ſtock, will anſwer the purpoſe beſt, on the particular deſcription of land upon which they are to be grazed; and next, what ſorts may pay the moſt in the conſumption of the produce.

“ In general, it will probably be found, that upon ſtrong florid paſtures of the drieſt kinds, the large ſorts of cattle, with ſome of the larger breeds of ſheep, will be the moſt ſuitable ſtock; but that where the graſs-lands are neither ſo luxuriant nor ſo dry, and upon turnip-lands, the ſmall Engliſh, Welſh, or Scotch cattle, with ſome of the ſmall breeds of ſheep, will be moſt profitable. Thus, as different ſorts of graſs-land and different kinds of produce ſeem in point of profit to require different deſcriptions of animals to feed upon and conſume their produce, it is of much importance to be at ſome pains to make the beſt and moſt ſuitable application.” And in caſes where the grazier breeds his own ſtock, he will have little difficulty in ſelecting ſuch of the different kinds as are the moſt adapted to his views; but where the animals are to be purchaſed in, which muſt moſt frequently be the caſe, more care and circumſpection will be neceſſary. It will be proper, though a difficult taſk, to make a choice of ſuch as have been well kept and are in a thriving condition; as when they have been ſtinted in their food, and have the contrary appearance, they ſeldom do ſo well for the uſes of the grazier. It will likewiſe be of advantage to have them from ſituations in which the lands are inferior in point of richneſs. It is noticed by ſome, that many farmers have found great advantage in buying ſheep from the pooreſt ſpots, as they generally thrive moſt when they come into a richer paſture, like trees which endure tranſplanting the better for coming from a poor nurſery. They likewiſe think that they endure folding and penning better than ſheep which are bred on a more luxuriant ſoil. And they are certainly right, in theſe obſervations. But, with reſpect to the notion which farmers are apt to entertain, that all kinds of ſheep will not endure penning, they labour under an error. It is believed that all lean or ſtore-ſheep are the better for being folded. They are generally more healthy; and, above all other advantages, this one is certainly obtained by it; when ſuch ſheep are put to fatten they thrive much better and faſter, as oxen do that have been moderately worked. But where the grazing-lands are very moiſt, ſheep are not by any means a ſort of ſtock to be depended upon, as they are extremely liable to become diſeaſed.

In addition to theſe points, it is neceſſary to have conſiderable regard to the qualities or properties of the kinds of animals, whatever they may be, in the intention of grazing them with profit; thoſe kinds, whether of cattle or ſheep, which have the property of keeping themſelves fat, or in tolerably full condition, by the leaſt conſumption or expenditure of food, being conſtantly preferred, whatever the ſize or breed may be, as that is evidently a quality of much greater importance to the grazier than that of mere ſize, conſidered in an abſtract manner. It is ſtated, that where there are fine and rich paſtures, the grazier may “ chooſe his beaſts as large as he can find them, provided they are of the right breed and ſhape; but let him always prefer ſhape to ſize; for it will aſſuredly pay him better;” and, that “ thoſe who are upon indifferent graſs muſt take care to proportion the ſize of their beaſts to the goodneſs of their paſtures: their cattle had much better be too ſmall than too large; as there are vaſt tracts of land that will anſwer in grazing, which are not good enough to ſupport large breeds.” And it is not improbable, but that the ſame thing may hold good in a great degree in regard to ſheep. But in all ſuch caſes, as where the ſtock is reared upon the land of the farm, which is often a good practice, there can be little difficulty, as has been ſeen, in fixing upon ſuch animals as are the moſt proper in theſe different intentions; but as it muſt often be neceſſary for the grazing farmer to purchaſe his live-ſtock at fairs and markets, and in other circumſtances, much care and attention, as well as knowledge, will be required for him to accompliſh it in the moſt advantageous manner.

In a ſyſtem of Practical Agriculture, lately publiſhed, it is noticed to be “ of great importance in this buſineſs to provide ſuch as have been kept in a proper manner, and are in a healthy, improving ſtate; as, where the contrary is the caſe, they are difficult, and require a much greater length of time to be brought into the ſtate proper for ſale than would otherwiſe have been neceſſary. It is, perhaps, experience alone that can qualify the grazier to form a correct judgment in theſe reſpects; in general, however, he is led to the choice of ſtock by no fixed or ſcientific principles, but by the impreſſion the appearances of the animals have upon him.” And, it is ſtated on the authority of Mr. Marſhall, “ that the experienced grazier, who has been accuſtomed to attend fairs and markets, knows at ſight, or by the aſſiſtance of the ſlighteſt touch, whether the animals he is about to purchaſe will ſuit him. Their general form and looks pleaſe him. They are every where clean; have little offal about them; their eyes are full and vivid; their countenances briſk; their ſkins alive, and their fleſh mellow. On the whole, they have the reſemblance of thoſe which have been grazed before with ſucceſs. Others are rejected, from the grazier not having found any ſuch as they reſemble to have done well, but many to have turned out in an unprofitable manner.” And the writer of the above work conceives, that there are certain “ principles in this branch of the farmer's buſineſs which may be attended to with great advantage, as the animals have certain points or parts, the proper or improper forms of which denote them to be valuable, or the contrary, for this purpoſe. Theſe are, that the legs ſhould be ſhort in proportion to the ſize of the animal; the back very ſtraight, broad, and flat; the loins wide; the carcaſe deep round, or rather barrel-ſhaped below; the fore-quarters round, full, and ſpreading; the bones ſmall; the fleſh affording an elaſtic feel; the ſkin thin, and a diſpoſition to fatten well, and on the beſt parts. Where theſe marks are predominant, the ſtock is moſtly ſuitable for the purpoſes of the graziers.” And, “ that where the hair of the hide, in fattening cattle, is inclined to curl inſtead of being ſtraight, they are moſt diſpoſed to thrive. This has been found to be the caſe in practice in different parts of the kingdom," as has been ſhewn in various publications on agriculture.

"In lean beaſts alſo, when the hair of the hides is curled, they commonly keep themſelves in better condition than where the contrary is the caſe. In all caſes a diſpoſition in the animals, of whatever ſort they may be, to wildneſs, and not remaining quietly in their paſtures, forms an inſurmountable objection in this ſyſtem of management; as no animal ever fattens well that has a tendency to ramble: it is quietneſs, feeding quickly, and lying much, that has the greateſt tendency to make them become fat in a ſhort time;" a fact which is fully confirmed by what happens in the new Leiceſter or Diſhley breed of ſheep, which are ſo tame and quiet as ſcarcely to move over a common gutter in the paſture. And, "from the reſult of actual experiment with four different beaſts, in which the leaſt poſſible difference could not be diſcovered on the moſt minute examination, it has been ſhewn that too much attention cannot be beſtowed in the choice of the breed of fattening ſtock, as, though they were in every reſpect the ſame in appearance, two, from their ſuperior diſpoſition to fatten, were found to afford a profit in the proportion of fifteen ſhillings the week, while the other two did not yield more than about five ſhillings and ten-pence." This fact is recorded in the Annals of Agriculture, and clearly ſhews that too much attention cannot be paid by the grazing farmer to the diſcovery of this propenſity in the ſtocking of his paſture, or other graſs-lands.

Notwithſtanding it muſt often happen that the grazier cannot fully avail himſelf of this, from the impoſſibility or vaſt difficulty of procuring ſuch animals, and is conſequently under the neceſſity of buying in ſuch as are more at hand, and ready for his uſe.

It is the uſual cuſtom in Leiceſterſhire, and the neighbouring diſtricts, to have commonly recourſe to the improved long-horned breed of cattle, from the animals being found to fatten in a ready manner, and to afford good beef. And, in the adjoining county of Lincolnſhire, a mixture of the large ſorts, of both the long and ſhort-horned breed, are had recourſe to as grazing ſtock, beſides thoſe bred in the county, and ſuch as are brought into it by the Sotch drovers.

On the contrary, in Somerſetſhire, the dark-red ſort, or Devonſhire breed, has been long much in eſteem by the graziers, and have lately ſpread themſelves much into the midland diſtricts, as Leiceſterſhire, Oxfordſhire, and Warwickſhire, from the grazing farmers in theſe diſtricts finding them to anſwer upon their paſtures more perfectly. And in Suſſex, the ſame breed is alſo held in conſiderable eſtimation by the farmers, as well as their own variety of it, as they are both found to fatten kindly, and with conſiderable expedition, upon their lands, and to have a ready ſale in their markets and fairs.

However, in the more arable or tillage diſtricts of Norfolk and Suffolk, where turnips and artificial graſſes are more in uſe, the Kiloe, Galloway, and other ſmall Scotch breeds, as well as thoſe of the Welſh runt kind, are in preferable demand, from their anſwering better on theſe ſorts of food, their more kindly diſpoſition to fatten, and the excellent quality of their fleſh, which never fails to have a ready ſale in the London market, where the greateſt part of their fat ſtock is ſold. But the grazing farmers in the northern counties have moſtly recourſe to their own long-horned breed, raiſed on the farms, with the different Scotch breeds brought into the diſtricts, their home ſort being in their experience the leaſt diſpoſed to take on fat and become ſaleable. And the large Hereford ſort, as well as that kind of Welſh cattle termed the Glamorgan, are alſo very advantageous grazing ſtock in ſituations where the paſtures are good, and they can be finiſhed with other ſorts of food. Great numbers of the former of theſe ſorts are purchaſed by the graziers round the metropolis for being fattened or brought conſiderably forward on the rich graſs lands, which have been mown for hay, and finiſhed with other ſorts of food. Yet the ſmall breeds of the Scotch, Welſh, or other ſimilar kinds, may, in many caſes of the inferior ſorts of grazing lands, often be the moſt beneficial in affording profit to the farmer, as he can ſuit them more to the nature and ſtate of ſuch lands, and they have more chance of becoming fat upon them. Indeed it has been ſtated in the tenth volume of the Bath Papers, on the experience of fifteen years, that the ſmall animal has *generally* "a more natural diſpoſition to fatten, and requires (proportionably to the large animal) leſs food to make it fat; conſequently the greater quantity of meat for conſumption can be made per acre." If this point was ſatisfactorily proved, there could be no doubt of ſmall animals being preferable both on this deſcription of grazing land, and that of a better quality; but, as an able and accurate obſerver has upon much experience been induced to think differently on this ſubject, the grazier ſhould be cautious how he has recourſe to ſmall breeds upon lands that are capable of fattening large ones, until the queſtion has been fully decided.

In reſpect to what relates to the ſort of cattle that may be employed to the greateſt advantage under this ſyſtem, oxen, and ſuch heifers as have been ſpayed, are in general conſidered, by the beſt informed graziers, as the beſt ſort of ſtock; as beſides being more quiet, the latter have not only the property of fattening in a more expeditious manner, but with a leſs conſumption of food. They are not, however, ſo readily provided by the grazier. The ox is of courſe the moſt commonly, as well as moſt extenſively, employed for the purpoſe of the grazier, as having the advantage of being capable of being fattened, and of affording good beef, after he has been beneficially wrought in the team of the farmer. Cows, under different circumſtances, are likewiſe often bought in by the grazing farmer for the purpoſe of being made fat, ſuch as thoſe that have become dry, have ſlipped the calf at an early period, or are becoming aged; but much caution is neceſſary in the purchaſe of this ſort of grazing ſtock, as they frequently turn out leſs favourably than bullocks or heifers, though in ſome caſes they leave a good profit. When old, they rarely thrive well or get fat with any degree of expedition. Indeed it is, perhaps, the beſt way, in all caſes, for the grazier to have ſuch ſtock as is not too far advanced in age, as young animals are invariably more diſpoſed to get fleſh, and become fat, than ſuch as are old. In the grazing of both heifers and cows, they ſhould be ſuffered to take the bull as ſoon as they have an inclination, and be ready for being ſold off fat ſeveral months before the time they would have calved. Such cow or heifer ſtock as are in calf, may ſometimes be purchaſed in at a cheap rate in the fairs in the autumnal ſeaſon, and be fattened off in the early ſpring with a good profit. There is likewiſe another deſcription of this ſort of ſtock ſometimes grazed, which is what are termed *free martins*, or cows that are barren; but they are ſaid to ſeldom anſwer in this intention in any very advantageous manner.

In relation to the moſt proper ſheep ſtock for the grazier, when the paſtures are rich, and afford full keep, the improved, large long-woolled breeds, as the new Leiceſters, may yield the beſt profit; but where the lands are leſs rich, and the feed of courſe leſs plentiful, the ſmall, improved, ſhort-woolled breeds, as the South Downs, may leave a more ample profit to the farmer. Where wethers of the former kind can be procured, they moſtly turn out well for the purpoſe. And in the contrary circumſtances, perhaps the South Downs cannot be excelled by any of the ſhort, or middle-woolled breeds. But in particular ſituations and circumſtances of graſs-lands, many other breeds may, however, be more profitable to the grazing farmer. It is ſtated, in the Agricultural Survey of Somerſetſhire, that the Dorſets, formerly ſo prevalent in that diſtrict, have lately given way to the polled, native breed of the lower part of the county; from the circumſtances of their giving a larger proportion of wool, and their fattening more expeditiouſly, and at the ſame time more fully, eſpecially on the internal parts. However, in the rich marſhes in the ſouthern parts of the iſland, the grazing farmers, who are moſtly in extenſive buſineſs, have conſtantly recourſe to the polled, white-faced breed, and that of the South Down, which they find the moſt profitable ſorts on their lands that can be employed.

In the northern parts of the kingdom, the graziers have principally recourſe to the native breeds, the heath and Cheviot ſorts, and find the former the quickeſt in getting fat, and the moſt hardy in their nature. The Cheviot ſort ſeems, however, lately to have gained ground in the more elevated and hilly ſituations.

Whatever the breeds of the animals may be that are made uſe of as grazing ſtock, it has been found, from long experience, that it is a matter of much importance to procure them from diſtricts, where the quality of the land is inferior to that on which they are to be fattened, as by ſuch means they not only get fat in a more expeditious manner, but without ſuffering any check upon being firſt turned upon the paſtures.

It is a matter of much conſequence in ſheep grazing that they have a fine cloſe paſture; and that they be prevented from going upon ſuch graſs-lands as have been covered by water, and become ſandy. as under ſuch circumſtances, they are liable to become diſeaſed. And, beſides this, it may be beneficial in many caſes for the farmer to be careful that horſes are not turned upon the paſtures along with them, as it has been found that the tufts of long, rank graſs that riſe about the dung-heaps, are apt to render them in a ſtate of diſeaſe, except where froſt has taken place, when the danger is for the moſt part removed; and it is ſuppoſed, that it is alſo dangerous to ſuffer ſheep to browſe upon the grain, eſpecially that of barley, which ſhoots up among the ſtubble, after the harveſt is completed; and fallows that are wet and unſound are equally detrimental, whether the ſoil be *light* or *ſtrong*. In the former ſituations, they frequently pull up the herbs by the roots, which they eat with the dirt adhering to them, which will inevitably give them the rot; and, if the fallows be ſtrong land, and ſhould not afford a ſufficient ſupply of food, they are liable to the hunger-rot, from being compelled to eat the rank, unwholeſome vegetables produced on ſuch grounds, eſpecially the leſſer ſpear-wort, and the marſh-penny-wort, both of which plants flouriſh in wet ſituations, and ought carefully to be eradicated wherever they are found. It is further adviſed, that in turning ſheep into paſtures, particularly water-meadows, and alſo into thoſe places that are ſubject to rot, to purſue the ſame precaution as with neat-cattle; which is previouſly to ſatisfy the craving of appetite, by giving them hay or cut ſtraw, and after the dew has been evaporated by the rays of the ſun, to drive them gently round the field for two or three hours before they are ſuffered to eat. But, whenever any ſort of dry food is given, they ought to be ſupplied with *pure water*, particularly during the intenſe heat that uſually prevails in the ſummer months, and which often renders the graſs as dry as a ſtubble. "For this purpoſe, clear, light-running water is always to be preferred, where it can be obtained; though, in general, whatever preſents itſelf is made uſe of. But where this neceſſary of life is found only in a tainted ſtate, or overcharged with the juice of dung, it will be adviſable to give them well-water in troughs or ſhallow tubs. This muſt be particularly attended to in the folds, ſo long as the ſheep are confined there by the ſeverity of the weather." It has been noticed, that "the watering of ſheep is, on the Continent, regarded as a circumſtance of the greateſt moment, and accordingly receives that attention which it requires. Thus, in Sweden, and at the national farm at Rambouillet in France, they are daily watered with running-water, or with that obtained from lakes or ſprings, *ſtagnant* water being moſt properly and rigorouſly prohibited. In ſome of the Saxon ſheep-farms, the ſheep are watered in the cots or folds during the winter, inſtead of taking them to watering-places. Spring or well-water is conducted by means of pipes into troughs, out of which the ſheep drink at pleaſure; they in conſequence drink oftener, and each time take leſs water, which is favourable to their health. The ordinary mode of watering ſheep in that, and we may add in many parts of our own country, is attended with many inconveniences. The animals refuſe to drink water in the winter, if it be too cold; they hurry while drinking, and do not take enough when the weather is very windy, or hail, rain or ſnow falls.

"Beſides which, they often diſturb the water with their feet; this diſguſts them, and at length one part of the flock completely prevents the other from approaching the watering-place." And it has been adviſed to fold them before the dew falls in ſummer and winter, and not remove them till it exhales, letting them have hay or other dry food of ſome ſort.

It is ſtated, that all grazing-land of rich quality ought to be ſtocked with ſheep, cattle, and horſes, ſo that the graſs may be eaten clean off; for, unleſs it is regularly depaſtured, much damage enſues. Each of the above three kinds of animals prefers, as moſt palatable food, ſome graſſes which the others reject; and none of them will bite near their own dung, though they may near that of others; and thus they conjointly contribute to keep the paſture level without much expence. Paſtures or grazing-lands ſhould be kept as level as a bowling-green, both for ornament and uſe; for, by one part being left higher than another, the long graſs keeps increaſing in patches; and land where it grows may be conſidered as taken away from the paſture, as the cattle will almoſt ſooner ſtarve than eat it. By leaving the ſort of graſſes the animals refuſe from year to year, the land increaſes in uſeleſs plants, and diminiſhes in uſeful ones; as the ſeed of ſuch plants continually drops, and the uſeful ones are prevented ſeeding by the cattle eating them. If ſuch paſtures were mown in thoſe places, it would give the uſeful plants room to grow. There are in this kingdom an infinite number of acres of rich and excellent land, which, from bad management, and from want of judgment in ſtocking, become of no more value than a barren ſoil. But ſuch grazing land as is intended for the purpoſe of feeding cattle, a few ſheep are conceived abſolutely neceſſary to eat up the weeds. If any part of the paſture be getting into bents, or higher graſs than it ought to be, and the animals begin to neglect it, you muſt mow it immediately, and as near the ground as poſſible; for the cloſer you cut down ſuch coarſe parts, the ſweeter and the quicker will the graſs ſpring up in the place. Could animals, by hunger, be driven to eat the long graſs, they would not fatten upon it; for, as the nearer the bone the ſweeter the fleſh, ſo the nearer the ground the ſweeter the graſs; it is not, he ſuppoſes, ſo much the quantity as the quality of the food that muſt be attended to.' And in further proof of the advantage of hard ſtocking, it is ſtated, that it is a common complaint, that the land is good in ſpring, but it goes off. Is this to be wondered at, when one-third, or perhaps one-half of the field is become ſo rank, that no one animal in the paſture will bite a mouthful of it? Suffer the very beſt piece of graſs-land, entirely free from weeds, to lie without either eating off the graſs, or mowing it, and in a few years it will be over-run with weeds, have very little uſeful graſs in it, and in fact be little better than rubbiſh. Conſequently, there can be little doubt of the beneficial conſequences of hard or cloſe ſtocking on the older ſorts of grazing-land; but on the new leys it ſhould probably be ſeldom attempted, as injury may be done to ſuch lands without the ſtock being thereby adequately improved.

But in grazing farms, there are ſeveral different ſyſtems of management purſued, in reſpect to cattle as well as ſheep. The practice with ſome graziers is, "to purchaſe their cattle in the fairs in the autumn-ſeaſon, about October, or in the following month, ſupporting them through the winter, principally with ſtraw, or ſometimes, which is a much better practice, with a little hay mixed with it, till towards the beginning of March, continuing their fattening through that and the ſucceeding month with ſome ſort of ſucculent food, ſuch as turnips, potatoes, or other ſimilar kinds, until the graſs be in a ſtate fit to be turned upon in May, on which they may be carried forward and completed, according to circumſtances, about Auguſt, or in the following month."

And another practice "is to purchaſe their beaſts lean, as ſoon as the graſs-lands are in a ſtate fit to be turned upon in May, wholly completing their fattening on the graſs about the latter end of October, or later in the autumn, according to their quickneſs in feeding. In this ſyſtem of management, the ſmaller kinds of cattle ſtock may be found in general the moſt advantageous, eſpecially where the lands are of the leſs fertile and luxuriant deſcriptions."

Another practice, ſometimes had recourſe to by grazing farmers, but which is, in general, perhaps leſs profitable than either of the above modes, is that of buying in ſtock at ſuch periods, according to the difference in their ſizes, as that they may be ready to be ſold off about April, or in the ſucceeding month, a period at which they uſually fetch high prices in the markets. It has been obſerved, that "in this ſyſtem, with large oxen or other ſorts of beaſts, it is ſometimes the practice to keep them through two winters, giving them only one ſummer's graſs; being in the firſt winter not fully fed, but kept in good graſs in the ſummer-ſeaſon, and forced on with the beſt feeding in the ſecond; but with the ſmaller ſorts of ſtock, one ſummer's graſs and a winter's ſtalling is the uſual mode; the cattle being bought in as ſoon in the ſpring as the graſs is riſen to a good bite." It is in very few inſtances that the animals can pay for this length of keeping. And, "in ſome diſtricts, heifers are preferred to oxen; in which caſe, they buy them in about March or April, and, after keeping them through the ſummer, ſell in October and November. This method is thought, by ſome, a profitable ſyſtem of management." By the author of the Modern Syſtem of Practical Agriculture, on theſe different ſyſtems, it is noticed that they may all "probably be practiſed with advantage under different circumſtances; but it is obvious that the firſt can only be had recourſe to with propriety, where green winter food is raiſed in ſufficient abundance, and the grazier has a ſtore of litter for being converted into manure. Under other circumſtances, the ſecond mode of management will be much more profitable. The two laſt methods are the leaſt convenient, and, probably, on the whole, except in very favourable circumſtances, the leaſt profitable, eſpecially the former of them, as, from the great length of time which they are kept, much management and attention to food becomes neceſſary to render them advantageous; which, with common ſervants, is ſeldom ſufficiently regarded."

But in addition to theſe ſeveral modes or plans of fattening neat-cattle, there is a practice followed in ſome rich hay-diſtricts near large towns, and particularly by the hay-farmers in Middleſex, which is, that "of buying in ſmall cattle in tolerable condition in the autumn, as ſoon as the after-graſs is ready, in order to their being fattened out on the rouens, and diſpoſed of towards the latter end of October, or beginning of the following month."

And, regarding ſheep ſtock, the ſame difference of ſyſtem takes place; as, in ſome caſes, where the lands are in a ſtate of incloſure, it is the "practice to buy ewes in lamb in the latter end of ſummer or beginning of autumn, keeping them on the inferior ſorts of graſs-lands, ſtubbles, or fallows, till the beginning of January; and then, by giving them turnips or cabbages, to keep them in good condition through the period of their lambing, and afterwards in the beſt manner that can be contrived, in order that the lambs may become fit for the butcher ſufficiently early to admit of the ewes being afterwards fattened, and diſpoſed of in the beginning of the autumn." This, in many caſes, is found a profitable ſyſtem of management, but which requires much care and attention in directing it.

Another practice in this buſineſs is, to purchaſe wether ſtock about the beginning of May, at the age of two or three years, keeping them ſparingly till ſome weeks after the grounds have been cleared from hay; then bringing them to good keep in the rouen, afterwards fattening them by means of turnips or cabbages, ſo as not to have them ready ſooner than the beginning of March, which is commonly the ſeaſon in which they fetch the higheſt prices. In this ſyſtem of grazing management, a good profit is moſtly afforded by farmers who purſue it in a judicious and ſteady manner.

And a further practice in fattening ſheep is purſued in ſome caſes with great profit and ſucceſs, which is that of buying in lambs of the wether, or other kinds, about the beginning of September, which are kept in different methods by different graziers, being by ſome brought forward with the greateſt poſſible expedition by the beſt keep, ſo as to be ready to be ſold off as ſoon as poſſible. But others have recourſe to the contrary method, keeping them only in a middling way during the winter, till about the beginning of April, and then forcing them forward by good keep, ſo as to have them ready for the butcher in Auguſt, or continuing them in the following month; and then clearing the whole of the ſtock from the land. In this practice, large profits are often made by judicious graziers, eſpecially when ſituated near large towns where the population is great.

Another ſyſtem of fattening, which can only be purſued to advantage in ſituations near large populous towns, is that of providing graſs-lambs for the markets as early as poſſible in the ſpring months, which pays the grazier well in many caſes. With this view, it is the practice to procure the more forward ewes, ſuch as thoſe of the Dorſet breed, which drop their lambs in the beginning of January, if not before. In Middleſex, where this management is much attended to, in conſequence of the great demand, it is the cuſtom to purchaſe this ſort of ewes at Kingſton, Weyhill, and other fairs in the neighbourhood. The ewes, in order that they may have a plentiful ſupply of milk, are extremely well kept on turnips, brewers' grains, and fine green ſweet rouen hay, and the lambs thereby forced forward in ſuch a rapid manner, as to be ready for the markets in the beginning of March or April. And the ewes, from their becoming dry ſo early, are capable of being fattened and diſpoſed of towards Michaelmas, uſually fetching the prices at which they were purchaſed in at: as the whole of the ſtock is in this ſyſtem cleared within the year, the farmer has the opportunity of fully aſcertaining its advantage or diſadvantage. The ſtatement of which is thus given in the able Survey of the Agriculture of the County of Middleſex:

Statement.	£.	*s.*	*d.*
Lamb, ſold at	1	10	0
Ewe, do. do.	1	10	0
Wool, 2*s.* 6*d.* or	0	2	0
Together	3	2	0
Deduct prime coſt	1	12	0
Remains the increaſe of an ewe in one year	1	10	0

It is hinted, that "in this management very much depends upon keeping the ewes perfectly well fed, and in dry warm incloſed paſtures, as without ſuch attention the ewes are apt to become thin and lean, in conſequence of the greatneſs of the evacuation, and afterward to require a much longer time in being made fat," by which much loſs muſt be ſuſtained. In the Economy of the Midland Counties, a practice in reſpect to fattening graſs-lambs, is ſuggeſted, which in particular caſes may be beneficial; which is that of removing the lambs from the ewes when they decline much in milk, before they are perfectly fattened, in order to complete them on young clover, or other ſorts of "prime keep." The chief object in this caſe is, that of the ewes becoming ſooner ready for the butcher. Some, alſo, conceive, that after the firſt fluſh of milk is gone, and it begins to be ſcanty, the lambs thrive better "on graſs alone, away from the ewes," than when kept along with them, as the hankering after the little milk that is afforded prevents their feeding freely on the graſs. Hence it is ſuppoſed, that "where this method is followed, which can probably be with advantage only where the milk of the ewes is greatly deficient in ſupporting and bringing the lambs forward, much attention muſt be paid to having the keep early and in abundance. In this view, rye-graſs and white clover for early uſe, and broad clover at a later period, may be the moſt proper and uſeful crops. In this management the ewes ſhould be carefully examined occaſionally; and, where much deficiency in the milk is found, the lambs be immediately removed to the paſtures."

In reſpect to the ſtocking of graſs-lands in the moſt advantageous manner for the grazier, it muſt depend materially on the richneſs of the lands, and the nature of the ſtock in reſpect to ſize, and other circumſtances. But, according to Mr. Billingſley, the Somerſetſhire graziers, in ſtocking the rich and middling ſorts of graſs-land, allow, to an ox, from one acre to an acre and a half; and ſome add one ſheep to each ox. But, in Lincolnſhire, they ſtock in much larger proportions; as is ſhewn in the Agricultural Survey of that diſtrict, where they are brought into a tabular form as below, for the more rich paſture land.

Table of Stocking rich Paſtures.

Names of places.	Sheep in ſummer per acre.	Acres per bullock in ſummer, with the ſheep.	Sheep in winter per acre.	Rent.
Long Sutton	5½	2½		
Mr. Scroop	11	No bullocks.		
Boſton, &c.	4	1½	2	
Skirbeck	5	1¼	2	
Bolton	5	1	3½	
Deeping Fen, Mr. Graves	5	2	1½	40
Alderchurch, Mr. Berridge	7½	2	3	
Swineſhead	2½	1	2	
Ewerby	3	2½	2	30
Horbling, &c.	3	2	2	
Howel	3	3	2	
Immingham	1	1½	2	
Grainthorp, &c.	3	3	1½	
Stallenborough	2	2	2	
Skidbrook	1½	1¼	½	
Ditto, &c.	2	2	—	35
Addlethorpe	5	1¼	2	40
Goſberton	6	1	2	
Burgh, &c.	5	2	2	40
Wrangle	2	2	—	36
Hundred of Skirbeck	2	1¼	2	45
Wibberton	5	2	2½	
Marſh Chapel	3	2	—	35
Ditto	3	1	—	45
Grimſby	2¼	1	2¾	
Average	3¾	1¾	2	

Upon this it is obſerved, that "conſidering the ſize of the ſheep, which cannot be eſtimated at leſs than 24lb. a quarter, on an average; and that the bullocks riſe from 50 to 100 ſtone (14lb.), this rate of ſtocking is very great indeed. There are, on every acre, 360lb. of mutton, and reckoning the bullocks at 42 ſtone, dead weight, there is alſo 336lb. of beef; in all, 696lb. of meat per acre in ſummer, beſides the winter produce, which is immenſe."

But, in the rich grazing counties in the more ſouthern parts of the iſland, a large proportion of both ſheep and cattle ſtock is admitted per acre: the exact proportion, however, differs with different graziers very greatly.

But the great and leading principle in this buſineſs is, however, never to ſtock in ſuch a manner as to reſtrict the animals in the leaſt; as it is by their being enabled to fill themſelves quickly, and to lie down much, that the greateſt progreſs and advancement in fattening are made, whether in ſtock of the cattle, ſheep, or any other ſort, when at graſs. But, on the inferior or weaker graſs-lands, a much ſmaller proportion of ſtock than on thoſe of the rich and fertile kind only can be employed. It can frequently not be more than an ox and a ſheep or two, to two acres, or two acres and a half. However, in ſtocking with neat-cattle, for the purpoſe of fattening, it ſhould conſtantly be ſuch as that the animals may have a full bite; but with ſheep, ſuch as to keep the paſture in a rather cloſe ſtate of feeding. Another circumſtance is neceſſary to be attended to, in order to bring the grazing-ſtock properly forward in paſtures, which is that of changing them more frequently than has generally been the caſe with grazing farmers. And it is, perhaps, on this principle, as well as thoſe of their affording greater degrees of warmth and ſhelter, and thereby promoting the growth of the herbage more abundantly, that ſmall incloſures are more advantageous in this practice than thoſe of a ſize larger. See Pasture.

But the practice of different diſtricts, where the grazing ſyſtem is much in uſe, will, however, afford a more clear idea of this ſort of management. In the Agricultural Survey of Lincolnſhire, it is ſtated, that in the low-land in Barton on the Humber, there was a horſe-paſture and a ſheep one contiguous, and upon the incloſure it was remarkable to obſerve the great difference between them; that which had been under ſheep ſo greatly ſuperior. And in the tract of marſh-land on the ſea-coaſt they obſerve, that, where moſt graſs is left in autumn, there the herbage is the coarſeſt and worſt next year. The remark was, it is obſerved, made in anſwer to recommending eddiſh for ſpring-feeding ſheep, which they thought would not do on rich marſh, though it might on uplands. This likewiſe ſhews that the Romney Marſh ſyſtem of cloſe feeding is right, and would anſwer as well in Lincolnſhire. And in the hundred of Skirbeck, they like, it is added, to have a tolerable head of graſs in the ſpring, before turning in; and afterwards ſo to ſtock as to prevent its getting coarſe by *running away*, ſo as to prevent the neceſſity of *hobbing*, which, however, muſt be done in a wet growing ſeaſon. Mr. Parkinſon obſerves, that the leſs ſheep are changed the better. This remark, which he takes to be very juſt, demands, he ſays, attention; it bears on the queſtion of folding. Beaſts are changed while *hobbing* is done; and the ſooner it is hobbed the better, as, if cut while young, cattle will eat it. But in Somerſetſhire, according to Mr. Billingſley, in ſummer feeding, attentive farmers have the dung which falls from the animal ſcraped up and wheeled into heaps, and the thiſtles and rough ſpots frequently mown. Beſides they make a point of excluding horſes and ſheep from their cow-paſtures. And when their mown ground is fit to be ſtocked, they hayn their ſummer leaze, ſo as to have a good ſupply of rough graſs or rouen in the winter. They alſo mow and feed alternately, by which means the beſt ſorts of graſſes are preſerved and encouraged; and in the Synopſis of Huſbandry, it is ſtated, that, "when the ſummer turns out moiſt and growing, the herbage often ſhoots faſter than the ſtock can eat it down. In this caſe it is common in Kent, to bruſh over the marſhes at the mowing ſeaſon, though they had not been originally laid in for that purpoſe; by which economy the farmer becomes poſſeſſed of a much larger portion of hay than he had before formed an expectation of, and which, in countries where this commodity fetches a good price, is an advantage whereof he is right to avail himſelf; for theſe caſual bruſhings may probably furniſh him with a quantity of winter provender ſufficient to his own uſe; whilſt thoſe marſhes which were primarily intended to be mown, and having been deſignedly laid in with that view, will produce a commodity of a better quality and more ſaleable; that may be diſpoſed of at market. On the removal of this old graſs, the ground is left at liberty to ſend forth a more vigorous ſhoot in the autumn, ſo that theſe rouens do at that time produce a ſweet and wholeſome paſturage, which would otherwiſe have been choked up with the rotten tore of the laſt year; yet there are caſes where it may be neceſſary to ſuffer this old graſs to remain on the ground, as where a portion of food is required for the cows or other horned beaſts in the winter. Then this old tore, having been ſweetened by the froſts, will be found exceedingly uſeful, and the cattle will at that time greedily devour what in the ſummer months they turned from with diſguſt."

The ſame writer alſo adds, that "the manner of ſtocking a grazing farm in the marſhes differs according to the nature of the land. In Romney Marſh, the views of the grazier are chiefly directed to the breeding and management of ſheep: and in the Iſle of Sheepey, both bullocks and ſheep claim his attention, whilſt in ſome parts the marſh land is wholly appropriated to the breeding of horned cattle and colts. Thoſe grazing farms are moſt eligible, which admit of breeding and fattening on the ſame paſture. This is the caſe with Romney Marſh, a tract of land ſo eminently diſtinguiſhed for a valuable breed of polled ſheep, that it furniſhes the graziers of Sheepey, and other places in this county, with an annual ſupply of lean-ſtock over and above what is reſerved for feeding; ſo that it is evident the grazier here enjoys a double profit from his farm, though it is believed, ſince the increaſed value of lean-ſheep, that the graziers in the Iſle of Sheepey have many of them adopted the method of breeding their own ſtock." This is probably the moſt beneficial practice.

In the county of Weſtmoreland, the cattle bought in in September are wintered on the coarſe paſtures and in the ſtraw-yard. In May following the young ones are ſent to the commons; and thoſe of an older deſcription turned upon the beſt paſtures as ſoon as poſſible, according to the earlineſs of the ſituation. But in the Agricultural Report of the North Riding of Yorkſhire, it is ſaid that "there the uſual time of breaking the paſtures is the 12th May, from which time they continue regularly ſtocked until about October, when, if the ſtock conſiſts of milch-cows, or feeding cattle and ſheep, they are removed to fog (after-graſs); the paſtures, with the addition of the ſtubbles, remain ſtocked during the winter with ſtore ſheep or lean cattle; but the latter are, by many farmers, taken into the ſtraw-yard for the night. The herbage of the paſtures is, however, it is thought, thus completely deſtroyed before winter, and the land thus left naked is ſtarved, and the growth of moſs greatly encouraged, to the almoſt certain ruin of the graſs-land. An inſtance has not occurred in the courſe of the ſurvey, of the practice of preſerving a conſiderable part of the ſummer growth of graſs upon the land, for ſpring feed, a practice well worthy of attention. This winter clothing, it is ſuppoſed, enriches the ſwards, deſtroys the moſs, and, by keeping the roots of the graſs warm, cauſes an early vegetation in ſpring, when the ſcarcity of the herbage ſo much enhances the value of it. On farms, the ſoil of which is not adapted to turnips, this practice would, it is ſaid, be peculiarly beneficial."

"In March, the land intended to be paſtured the enſuing ſummer, is, or ought to be freed, and the ſtock put into the land intended to be mown, where they remain, until thoſe paſtures are broken up in the beginning of May.

"In the dales of the Moorlands, the lower lands only are adapted to meadow; conſequently, the land cannot be changed alternately from meadow to paſture, as may be practiſed in many other parts of the Riding; though there, as before noticed, the practice is not ſufficiently attended to. There are many inſtances of cow-paſture, which have been invariably ſummer-fed during ſeveral generations." See Pasture-*Lands*.

"The beſt farmers uſually paſture their new laid ground the firſt two years, and that chiefly with ſheep, as ſheep improve graſs more than any other kind of ſtock, both by their treading more lightly and uniformly, and by the dung and urine being more regularly diſperſed over the land. But the practice of eating them very bare during the firſt autumn and winter after ſowing, and alſo mowing them the firſt ſummer, is too prevalent; ſuch practices are, it is obſerved,

ſerved, the ruin of ſeeds Some, however, think that paſturing new laid-ground is moſt excellent management; the ſeveral graſſes, by being frequently cropped, become not only firmer in nature, but much more numerous. Stock, when paſturing new lands, ought to be often changed; if ever you over-eat, they will require ſome time to recover their uſual vigour. New laid-grounds ſometimes give ſheep the rot, particularly three or four years laid, on indifferent ſoil."

And the practice of ſhifting the ſtock from one paſture to another, of mixing different kinds of ſtock together in a due proportion in the ſame paſture, and under ſtocking with ſheep, paſtures deſtined for feeding larger cattle, ſhould always be particularly attended to.

It is ſtated in the Survey of Lincolnſhire, that "the rich grazing lands are the glory of that county, and demand a ſingular attention. The ſoil is a rich loamy clay, ſome very ſtiff, but of uncommon fertility, as may be ſeen by various inſtances. Some of the grazing lands in Long Sutton that were common, will carry five or ſix ſheep an acre, and four bullocks to ten acres. Mr. Scrope has there four acres, which carry 45 ſheep in ſummer, and muſt be *hobbed* often to keep it down. And on the graſs-lands in Deeping Fen, improved by paring and burning, Mr. Graves keeps five ſheep an acre from Lady-day to Michaelmas, and one and a half in winter, and a bullock of 60 ſtone to two acres beſides in ſummer."

And from ſome trials which were made by T. Fydell, eſq. in the grazing of neat cattle on the beſt ſort of ground in Lincolnſhire, and which are given below, Mr. Young is led to conclude, that 3*l.* an acre is the higheſt rent he has heard of in that county, and much higher than common, even for the beſt lands. This ſeems to confirm the idea he has entertained, that the rich grazing lands of this diſtrict are lower rented than ſuch or nearly ſuch lands in other parts of the kingdom. And further, that "the average weight of the beaſts was 70 ſtone, being of the York or Lincoln breed; the ſheep all Lincolns. The former bought in April or May, and all gone by the 11th of December; the ſheep are bought in May; they are clipped twice, and ſold fat in April or in May following; that there is little difference in ſeaſons, except that, after a bad winter, the ſheep are not ready for market ſo ſoon by a month as they are after good winters. The loſs in weight in driving to Smithfield is very little; the expence, beaſts 15*s.* 9*d.* ſheep 1*s.* 9½*d.* each. Mr. Fydell held for ſeveral years a piece of land in Skirbeck pariſh, which meaſured 21 acres, and kept, *communibus annis*, from Lady-day to Michaelmas, 19 heavy beaſts, and a 100 ſheep, and wintered fifty ſheep. And he now holds a paſture adjoining his garden, at Boſton, of eight acres, which keeps in ſummer ten oxen and forty ſheep, and winters thirty ſheep. But the fineſt grazing lands are at Boſton, Alderchurch, Foſdyke, Sutherton, Kirton, Frampton, Wibberton, and Skirbeck: theſe will carry, in ſummer, a bullock to an acre and a half, beſides four ſheep an acre; and two ſheep an acre in the winter ſeaſon."

It is ſtated that "the Rev. Mr. Berridge, of Alderchurch, has near his houſe forty acres of the rich graſs, upon which the ſtock is upon an average 300 ſheep, ſixteen fattening bullocks, three cows, four horſes, and carries through the winter three ſheep an acre. This land is valued at 40*s.* an acre. It is a vaſt ſtock. He favoured him with theſe particulars in the preſence of a dozen neighbours, and called in his manager to confirm it; it wanted, therefore, no after-corrections." And "in the grazing lands at Swineſhead, a beaſt an acre of 40 to 70 ſtone, and two or three ſheep; alſo two ſheep an acre in winter. Mr. Tindal, at Ewerby, which is on high-land, compared with Holland Fen, ſtocks a bullock to two and a half acres, and three ſheep per acre in ſummer, and two ſheep an acre in winter. And in the lordſhips of Horbling, Billingborough, Berthorp, Sempringham, Pointon, Dowſby, Dunſby, and Hackonby, there are extenſive tracts of rich grazing land applied to fattening bullocks and ſheep, carrying a bullock to two acres, and three ſheep per acre in ſummer; and two ſheep an acre in winter, which lands are generally rented at 30*s.* per acre. Mr. Elkington, of Howel, keeps one bullock and nine ſheep to three acres, and in the winter two ſheep an acre." But "Hanworth, north of Lincoln, is chiefly graſs which is fed by cows, calves, and young cattle. On the Lawn at Norton Place, which is heath-land, two couples per acre in ſummer; but the ſoil not adapted to permanent graſs without great exertion." And "there is a tract of paſture-land, which is of conſiderable extent north and ſouth, but very narrow eaſt and weſt, which lies in the vale between the heath and the Wolds. He viewed it from Norton Place in going to Owerſby, which is in it; the quality is good, but of the ſecond rate." And further, that "the graſs-land cloſe to Gainſborough lets at 4*l.* and 5*l.* an acre. The marſh graſs on the Trent and Knaith, &c. 20*s.* to 30*s.* and produces one and a half or two tons of hay an acre. The marſhes on the river are ſtocked from the 12th of April to the 12th of May; this of late has, however, been omitted, as they found the graſs hurt by it. Clear the hay by Lammas, one to one and a half ton an acre. Then turn in milch-cows, and afterwards other ſtock, till November. Rent 20*s.* but meaſure ſhort. And at Garthorpe, in marſh-lands, ſome rich grazing lands, which will carry a good bullock an acre, but no ſheep fed. This land is now let to break up at 3*l.* 15*s.* an acre for 14 years." But that "Mr. Heſſelden, at Barton, has four acres near the town; levelled and manured it after the allotment, and this year it feeds four cows: three of them joiſted at 3*s.* a week, a produce of 12 guineas. At Immingham and Stallenborough, there are ſome marſh-lands that will carry nine bullocks of 80 ſtone upon 12 acres, and 12 ſheep, and two ſheep per acre in winter; ſome has only one. But the ſame lordſhips have, it is remarked, clay paſtures that will not do any thing like this. And, at Thornton college, Mr. Uppleby has a few cloſes of extraordinary fine grazing-land, which will carry the largeſt bullocks, and it is worth, he thinks, 50*s.* an acre rent.

"The marſh on the coaſt of Grainthorpe, Saltfleetby, and Theddlethorpe, &c. is very good: it will keep three ſheep an acre, and an ox to three acres; and one ſheep and an half to an acre in winter. The hilly wold good paſtures on marl and chalk at Gayton, near Louth, will carry three ewes and three lambs *per* acre, and a ſprinkling of young cattle, &c. beſides; ſome only two ewes and lambs, beſides cattle, ſuch land as is worth 15*s.* to 20*s.* an acre. In the marſhes that are in the vicinity of Saltfleet and Sutton, there is ſome diſtinction, which it will be proper to note by pariſhes. In Northcots, the quality rather inferior, being chiefly for breeding. Mars Chapel, better, but ſtill weak; and for breeding alſo. In Grainthorpe, a great deal very good grazing land. Coniſholm, low, ſwampy, and but little good. Skidbrook, a great deal, and very good. South Somercots, the ſame; but 1000 acres of *ings*, or common meadow. The three Saltfleetby's 5000 acres, and a great deal very ſtrong and good for feeding beaſts. Some of the late Mr. Chaplin's marſhes here ſold ſo high as 77*l.* the ſtatute acre. In general, the meaſure ſhort from Saltfleet to Sutton, there ſtatute. In the Theddlethorpes, much very good; but ſome low, and not well drained. Marblethorpe, very good. Sutton, remarkable good and ſtrong feeding land.

"In theſe marſh pariſhes, the rich grazing ground of the firſt quality lets at about 40*s.* an acre, and the reſt about 30*s.* Such as will not feed, but only breed, at 20*s.* to 25*s.*; and this diſtinction of feeding and breeding is here alſo expreſſed by ſaying, that one ſort of marſh will feed ſheep; but the other, keep them in holding order, will make them hold the fleſh they have got, but not fatten profitably. If the beſt of theſe lands are compared with the grazing diſtricts of Boſton and its vicinity, it was remarked to him, that theſe are more naturally good, and much better watered: they have at all times plenty of freſh water here, which is a great object; but for artificial fertility, locality to fairs and markets, &c. the Boſton lands are much ſuperior. The meaſure at Boſton, &c. is here ſaid to be more than an acre; here leſs, not more than three roods, and the *ing* land ſtill leſs. On ten acres, at Skidbrook, eight beaſts and ſixteen ſheep have been ſummered, and the ſheep wintered alſo. And, in general, the marſh that lets from 30*s.* to 40*s.* will carry a beaſt to two acres, and two ſheep an acre; but, perhaps, he ſays, more generally one and a half ſheep."

With reſpect to the profit of grazing the beſt land, it is ſtated in this manner:

Here the total intereſt made is about 9*l. per cent.* on the capital of 26*l.*, and this ſeems to be rather inadequate, for there is nothing for loſſes, which, in a courſe of time, muſt be ſomething conſiderable. The intereſt made ought to be, at leaſt, 10*l. per cent.* after a proper deduction for loſſes. Either, therefore, the land carries more ſtock, or it is too highly rented. Grazing is accounted a profitable profeſſion; but when it is conſidered that this 26*l.* capital would ſtock five acres of good arable land, and that they could not be reckoned to pay a leſs profit than from 12*s.* to 15*s.* an acre, from 3*l.* to 4*l.* 5*s.* it will appear that the plough is much more beneficial than ſuch grazing calculated in this way.

Mr. Kerſhaw, of Driby, and Mr. Bourne, of Haugh, agree in the following marſh account for land there at 35*s.* the acre.

The groſs intereſt rather better than 10*l. per cent.*

Mr. Parkinſon, of Reeveſby, obſerved, that the rich marſhes were better managed, and in better order, twenty years ago, than they are at preſent; the wold farmers had not then got ſuch poſſeſſion of them, and they were in the hands of reſident graziers, who attend much more to *hobbing*, which kept them fine; for nothing hurts marſh land ſo much as letting it run coarſe, from permitting the graſs to get a head. And he calculates an acre of rich marſh in Wrangle, &c. thus,

Or total intereſt 11*l.* 5*s.* 6*d. per cent.*

In the hundred of Skirbeck, the paſture conſiſts of three ſorts in point of rent, &c. the higheſt at about 45*s.* being from 32*s.* to 50*s.* The ſecond from 26*s.* to 32*s.* average 28*s.* The third, average 1*l.* 1*s.* Beſides this a ſmall quantity of open meadow, called *ings*, average about 18*s.* The beſt kind of paſture is chiefly ſtocked with ſhearling wethers, bought at the ſpring market at Boſton, which, having yielded two fleeces of wool, are ſold off eaſily in the next year; and by beaſts in the ſummer, ſold in autumn; ſome kept on farther in eddiſh, but all gone in the winter. The ſecond beſt is chiefly fed by young beaſts and hogs, kept on to ſhearlings: theſe are well kept, as their value materially depends on it; there are alſo ſome few breeding ſheep on this diviſion of the paſture. The third claſs is chiefly mown. But it is to be noted that all theſe particulars relate to an acre larger than ſtatute meaſure, about 4¾ roods."

"The firſt diviſion is ſtocked at the rate of three ſheep per acre, winter and ſummer, with the overplus of ſome bought in the ſpring, and not cleared from the land till ſome months later than the time at which they are bought. The beaſts are in proportion, on an average of ſeven to ten acres, from 54 to 100 ſtone. The ſecond claſs winters about five ſheep to two acres, with not leſs than four per acre in ſummer, with a few cows and young beaſts; and on both theſe there will be ſome few horſes, too uncertain to average. On the beſt land, they are chiefly horſes making up for ſale; and, on the ſecond quality, horſes employed in work, or young ones; it is not uſual to keep any horſes in ſummer except on the paſtures. The produce of hay on the third may be about 35*s.* an acre; the eddiſh eaten by cattle from the other grounds; or by lambs or hogs, before they go to their winter keeping.

The writer hints that the profit upon this firſt claſs of land is greater than upon the reſt; and that the third ſort yields very little profit by grazing, and would pay much better in tillage. There are many graziers there, who have no other land than what is upon theſe flats, and ſome who are ſuppoſed to have made by their buſineſs enough to have realized a comfortable ſubſiſtence. The grazing accounts of certain fields in the occupation of Mr. Loft, of Maſh Chapel, are ſtated in this way :

It is however ſtated, that very few fields will yield any thing like this: he has but one cloſe; and there are ſome expences omitted. And “ Mr. Tenniſon, of Lincoln, has 13 acres of marſh at Grimſby, that ſummer-feeds 14 bullocks; and carries 35 ſheep the year through.” But that “ in the tract of marſh-land on the ſea-coaſt, they obſerve, that where moſt graſs is left in autumn, there the herbage is the coarſeſt and worſt next year; the remark was made in anſwer to recommending eddiſh for ſpring-feeding ſheep, which would not do on rich marſh, though it might on uplands.” It alſo ſhews, that the ſyſtem of cloſe feeding is proper, and would anſwer well in many diſtricts where it is not the practice.” And “ in the hundred of Skirbeck, they like to have a tolerable head of graſs in the ſpring, before turning in; and afterwards ſo to ſtock as to prevent its getting coarſe by running away, ſo as to prevent the neceſſity of hobbing, which, however, muſt be done in a wet growing ſeaſon.”

But after the ſtock has been brought into a proper ſtate for the market, there is in many ſituations much difficulty in diſpoſing of it to the beſt advantage. Mr. Marſhall has remarked, that though it be attended with leſs difficulty than that of buying in the ſtock, it requires much knowledge, as well as experience, to execute it in the beſt manner, or with the leaſt poſſible loſs. A due conſideration of the progreſs of the ſtock while feeding, and of the length of time they have been upon the land, may afford ſome ſort of guide in the buſineſs; but the moſt correct judgment may be formed by the young grazier, by the practice of frequent weighing, and the accurate compariſon of the living with the dead weight of ſuch ſtock as are killed in his neighbourhood, as it is a much more certain method than the uſe of the eye and hand, as has been ſhewn under the head GRAZIER. Having recourſe to frequent weighing has alſo the advantage of ſhewing the progreſs that is made by animals under different ſorts of keep or food. But beſides this, the grazing farmer muſt be regulated in the ſale of his ſtock by the nature of his ſituation. In moſt of the midland and ſouthern parts of the kingdom, Smithfield is the place where the fat ſtock of the farmers are diſpoſed of: while in other parts, they are frequently ſold in the neighbourhood, or to the large towns which are at no great diſtance. In the former caſes, eſpecially on the leſs extenſive farms, the fat ſtock are brought up by perſons, who make it a buſineſs, being employed by various graziers in the ſame vicinity, who have an entire confidence in them. With the more extenſive graziers, who ſend up frequent lots, the buſineſs is done by a ſaleſman, in whom they have confidence. With little grazing farms, the cuſtom is often to ſell them to the butchers in the neighbourhood, which is frequently the beſt method. And the advantages of theſe different modes muſt depend greatly upon circumſtances. Some, however, ſuppoſe that the London market is the beſt calculated only for thoſe who give a weekly attendance, on account of the uncertainty of the ſupplies. The expences being materially different, as with the ſaleſman's commiſſion, they frequently amount to twelve ſhillings a head there, while in the country they are not more than from three to five. Conſequently, that fat ſtock may in many caſes, where only a few, or what are termed ſmall lots, are to be diſpoſed of, be ſold at home with leſs expence than having them ſent to diſtant markets; but that with large lots, the latter mode muſt be had recourſe to, as more certain, expeditious, and convenient. Upon the whole, the facts which have been ſtated fully ſhew that the advantages of the grazing ſyſtem muſt be materially different under different circumſtances, and be greatly influenced by thoſe of a local kind. It has indeed been remarked by a Kentiſh grazier, that the profits of no two grazing farmers are exactly “ alike on the ſame given quantity of land,” nor even on the ſame land, as years, prices, as well as the exertions and talents of each individual, are different. In all caſes, the ſuperiority of the ſucceſs muſt in a great meaſure depend upon the knowledge, exertion, and excellence of the method which is adopted by the particular farmer. Statements can of courſe only ſhew what are the general profits of the ſyſtem. With neat-cattle, in the weſtern and midland diſtricts, they are given by Mr. Billingſley, and Mr. Young, in the Surveys under the direction of the Board of Agriculture. In this way, the former ſays, that a grazing farmer who has 200 acres of land, may fatten annually one hundred head of cattle, as oxen, with ſeventy ſheep and ten colts, which together may afford a comfortable but not exorbitant profit to him.

By profit on two hundred ſheep winter fatted, and ſold in April unſhorn - -	100	0	0
	1730	0	0

And on the rich grazing lands in Lincolnſhire, according to the latter writer, the practice ſeems to afford a much greater advantage to the farmer; as the account, given by T. Fydell, eſq. M. P. for twenty acres, in 1796, ſtands thus:

Statement.

Dr.	£.	s.	d.
To 18 beaſts, at 12*l.* each - -	216	0	0
To 80 ſheep, at 46*s.* - - -	184	0	0
	400	0	0

Expences, viz.	£.	s.	d.	£.	s.	d.
Tithe - - -	1	10	0			
Dyke-reeve - -	3	0	0			
Rates - - -	10	0	0			
Shepherding - -	3	0	0			
Expences - -	5	0	0			
				22	10	0
Loſs, ſuppoſed one ſheep - -				2	6	0
				424	16	0
Intereſt one year - - -				21	4	0
One year's rent - - -				60	0	0
				506	0	0
Hire of a cloſe for the winter, for 35 ſheep - - - -				17	10	0
				523	10	0
Profit - - - - -				87	4	0
				610	14	0

Cr.	£.	s.	d
By 18 beaſts, at 19*l.* 5*s.* - -	346	10	0
By 80 ſheep, at 55*s.* - - -	220	0	0
By 52 tod of wool, at 17*s.* - -	44	4	0
	610	14	0

And that "the difference between the buying and ſelling price, loſs deducted, 208*l.* 8*s.*, is the produce of the land, or 10*l.* 8*s.* per acre, which is very great indeed, and ſhews that this land would let at 5*l.* 4*s.* an acre, ſuppoſing this year to be an average one.

"This difference of rent would deduct 44*l.* from the profit of 87*l.* and leave 43*l.* which, with 21*l.* charged, make 64*l*; intereſt on the year's advance of 546, or 11½ per cent."

But in the ſyſtem of grazing purſued in ſome of the ſouthern rich marſhy diſtricts with ſheep, as ſtated ſome time ago, the amount ſtands as below, according to Mr. Price; but at preſent the profit muſt be much higher, from the improved management of the Romney Marſh graziers in general.

Account of Stock bought in for Fifty Acres of Paſture Land, for the Year 1778.

	£.	s.	d
310 barren ewes, at 1*l.* 1*s.* each - -	325	10	0

It is remarked, "on the firſt of theſe ſtatements, that the year was favourable for vegetation; and that ſuch profits could not probably be made ſeven years together, which is the moſt accurate method of calculating profits on land. There being no aſſeſſes on the land, alſo, makes it more profitable." And further, that two modes in reſpect "to the profits on fattening land are ſtated; the firſt uſed by the beſt graziers; the other, the moſt common: ſome take bullocks in to keep, others buy runts; the profits of which muſt depend on their judgment; but 3*l.* is the medium profit between the whole: 10*s.* each ſheep is generally allowed as the gained profit by fattening." It is added that "it cannot be ſuppoſed that this profit will always amount to ſo much as the years differ; therefore dry ſeaſons will abate it, and a large tract of land cannot have the ſupply of ſtock to make it ſo great. There are loſſes to be taken out; but, upon the whole, it is very profitable, as the expences are ſo moderate, that one ſervant-man can manage a thouſand acres of paſture-land. The value or rent of land is put too low, except for long leaſes unexpired, or where a large quantity of land is taken. The average price of rent is from 40*s.* to 3*l.* for fattening land, unleſs four or five hundred acres of breeding and fattening, perhaps about 30*s.*; and ſome old leaſes 1*l.* breeding land."

It is ſtated that where ſheep, in order to fatten them in a more expeditious manner, or to finiſh them in caſes where the graſs is inſufficient for the purpoſe, have the addition of turnips or other ſorts of luxuriant green food, great care ſhould be taken, by the grazier, that a due proportion of ſome ſort of dry material be had recourſe to at the ſame time; as without ſuch precaution, not only loſs may be ſuſtained by the death of ſome of the ſheep in particular inſtances, but by their making leſs progreſs in becoming fat than would otherwiſe be the caſe. Hay, cut chaff, bran, or a few oats, anſwer the purpoſe very well. See SOILING.

It is neceſſary, in order that the conſumption of theſe ſorts of food may be conducted in the moſt economical manner, that proper troughs, racks, cribs, or baſkets, ſhould be provided, and fixed in ſuch a way, as that they cannot be overturned. The graziers, in ſome parts of Lincolnſhire, have a large ſort of crib or wicker-work baſket, being eight or ten feet in circumference, and wattled to the height of one foot or a foot and a half, in a cloſe manner, and then left open for about a foot and a half; after which it is cloſely wattled again for nearly a foot, being drawn in, in a narrowing manner at the top, ſo as to have only proper room for introducing the food. The ſtuds or ſtaves are placed about eight or ten inches apart, which admit of the ſheep feeding in a diſtinct manner. It is deſcribed in the fourth volume of the firſt ſeries of the Repertory of Arts, &c. and denominated a *tumbril.* It may be ſeen at *fig.* 8. in the *Plate on Granaries.* This contrivance affords much advantage, both in the ſaving of food from being waſted, and in affording the leſs ſtrong ſheep an opportunity of feeding without being diſturbed or driven away by the ſtrong ones, and conſequently much injured.

In the Rural Economy of the Midland Counties, it is noticed in reſpect to the practice of grazing in ſuch ſeaſons as are very wet, that an incident of this ſort that occurred to the writer in the very wet autumn of 1789 is intereſting. "The general complaint is, that grazing ſtock, though they have this year rolled in graſs, have not done well; Mr. Henton, of Hoby in Leiceſterſhire, being ſingular in ſaying, that his feeders had done tolerably. Indeed his ſtock corrobates his aſſertion. He had a lot of cows at Loughborough, the 12th of Auguſt, the fatteſt in the ſhow.

"But his management is more remarkable than his ſucceſs." He "foddered them with hay all the wet weather; that is, he mowed the broken graſs for them, beginning under the hedges, and continuing to mow the coarſeſt patches throughout the piece.

"The firſt day (the day it was mown), the cattle ſeldom touched it; but the ſecond or third day they fell to it freely, eating it "between whiles," in preference to graſs. In the morning, it was always the firſt thing they filled their bellies with.

"The cattle having eaten up the more palatable parts of the herbage, the thiſtles, and other offal, were raked up, and carried off the ground: moſt excellent management!

"This ſtock conſiſted of about ſixty head. At firſt one man only was employed in mowing, &c. But, before the rainy weather ceaſed, he ſet on another man.

"What an admirable thought! that which other men ſuffered to ſtand waſte in itſelf, an encumbrance to the ground, and a nurſery of weeds, was converted to food, more nutritious, in a wet ſeaſon, than the beſt of the ſtanding herbage."

Mr. Parkinſon, of Lincolnſhire, had made a practical obſervation, which is, that "the leſs ſheep are changed, the better." It demands the farmer's attention, as ſhewing the injury of folding in many caſes. And it is noticed, that the grazing cattle are changed while the buſineſs of *hobbing* the fields is performed, and that the ſooner this is executed the better; as when the graſs tufts are cut while young, the cattle will eat the produce well.

Upon the ſubject of ſtocking grazing land, Mr. Marſhall remarks, that "the fairs at Birmingham are among the worſt in the country for fat ſtock, the butchers giving the graziers no encouragement to drive their ſtock to them, preferring the toil of riding twenty, thirty, or perhaps forty, miles from home to pick up their "fat!" ſpending a principal part of their time and their profits in an employment truly ridiculous. How convenient it would be to the grazier, as well as to the butcher, to have a weekly market, a Smithfield at or near Birmingham! to the grazier, in thereby having a conſtant and certain market whenever he wanted either keep or money; and, to the butcher, in ſaving time and travelling expences. Yet the few animals which are taken there at preſent, are frequently drove out unſold. But Thurſday, which is the ordinary market-day, is improper. Monday or Tueſday would be a more ſuitable day; and Sutton, perhaps, the moſt ſuitable place. In performing the buſineſs of purchaſing in ſtock, the neareſt fairs are always to be preferred, if it can be done there with propriety; as much injury and loſs is frequently ſuſtained by driving from a conſiderable diſtance.

And the buſineſs of grazing other ſorts of animals may, in ſome caſes, be a profitable concern, but muſt always be regulated by the nature of the land and circumſtances of the farmer. Where he has a conſiderable extent of the more coarſe ſort of paſture-land, he may often find it advantageous to graze young horſes, eſpecially where he has the convenience of breeding them likewiſe. But though it is a practice ſometimes followed by grazing farmers, to admit horſes in the ſame paſtures with the other ſtock, it ſhould conſtantly be avoided as much as poſſible, as they are very injurious by teazing and driving the fattening cattle about, and preventing their reſting ſo much as is otherwiſe the caſe. It is a better method to let them follow this ſort of ſtock. When horſes are admitted upon the grazing lands in Somerſetſhire, it is ſeldom done in a larger proportion than that of one to twenty acres. But there is another animal which it has long been a practice in particular ſituations to graze. This is the hog, which, where the farmer has a piece of rich graſs, either of the artificial or natural kind, he may turn upon it with much advantage. With clover, and ſome other artificial graſſes, the animals are found to ſucceed perfectly well in this ſort of management; but it is objectionable as loſing a vaſt ſource of manure of an excellent kind. When the field is ſo ſituated as that the hogs can return in the evenings to the well littered ſties, it may, however, be a highly beneficial ſyſtem of practice. There can be no doubt but that this ſort of management might be much more extenſively employed with this animal, and that thereby much of the food of ſtore pigs might be ſaved. See Hog.

GRAZIOSO, *Ital.* *Gracieuſement*, *Fr.* graceful, are terms in *Muſic*, addreſſed to the performer; but if the compoſition is devoid of *grace*, the term can convey no inſtruction to the performer. It is in vain for the compoſer to ſit down with a reſolution to compoſe a *graceful* movement; it muſt come unſought, and inſenſibly.

Marmontel has defined grace in poetry, grace in attitudes, grace in motion, grace in the arrangement of words in proſe, of figures in painting, as a poliſh, a lacquer, a varniſh, a gilding to every human action; without which we may be ſurpriſed and entertained, but never perfectly pleaſed.

No poet, perhaps, abounds in grace and facility ſo much as Metaſtaſio; for examples, ſee his cantatas.

Among muſical compoſers, perhaps, none have been more gifted with this charm than Pergoleſi, Sacchini, and Cimaroſa.

The time of a gracioſo movement is nearly the ſame as *andante*; ſmooth, gentle, and inclined to piano; no coarſe ſtrokes of the bow on the violin, or dry *coups de langue* on the G flute, except, to vary the expreſſion and effect, the compoſer indicates the contrary.

GRAZZANO, in *Geography*, a town of Italy; 13 miles S.S.W. of Verona.

GRAZZINI, Gio. Paolo, of Ferrara, in *Biography*, left the profeſſion of goldſmith to become a painter at an advanced period of his life; his chief inſtructions he owed to the friendſhip of Carlo Bonone. The firſt ſpecimen of his capacity was a picture of St. Eligio placed in the goldſmith's hall of Ferrara. Eight years which he had employed to finiſh the work were amply redeemed by the diſplay of a maſter-hand, and a tone of colour that placed him near in rank to Pordenone, and aſtoniſhed all Ferrara, who had known Grazzini for half a century. He continued to produce works of leſs compaſs, but of equal taſte, which are met with in private collections. He died in 1632. Fuſeli's Pilkington.

Grazzini, Anthony-Francis, ſurnamed *Il Laſca*, an Italian writer, was born at Florence in 1503, and is known to poſterity as a conſiderable writer in proſe and verſe. He is particularly remembered for his light and jocoſe poems, among which are many of the Canti Carnaſcialeſchi, or Carnival Songs. Theſe, it is ſaid, were firſt invented by Lorenzo de Medici, and a collection of them was publiſhed by Grazzini at Florence in 1559. His other works are as follow: "La Guerra de Moſtri, poema giocoſo," 1584. "Stanze," &c. "Comedie VII.;" "Il Laſca, Dialogolo," &c.; "Lettere," "Orazione," "Rime," Novelle XI. The laſt was an extremely popular work, and as a noveliſt Grazzini was thought to be a worthy rival of Boccace in the elegance of his narration and purity of his ſtyle. He was one of the founders of the academy Della Cruſca. Moreri.

GREASE, among *Farriers*, &c. an inflammation and ſwelling of the heels about the fetlocks, and ſometimes of the legs of a horſe, as high as the knee or hock, with the ſecretion of an oily matter, to which the diſeaſe owes its name. The matter diſcharged from the heels has a peculiar offenſive ſmell, and the heels themſelves are ſometimes ulcerated. Heavy horſes, with round fleſhy legs, are the moſt ſubject to this diſorder, and the white legs more than the reſt. It is almoſt always found in the poſterior extremities. Greaſe is occaſioned by ſudden changes from a cold to a hot temperature, ſuch as the removing of horſes from graſs into hot ſtables; from the too ſudden change of a generous to an impoveriſhing diet; from neglect on the part of grooms in leaving the heels wet and full of ſand; and from conſtitutional debility. On the approach of this diſeaſe, and for ſeveral days before any very conſiderable appearances of ſwelling and inflammation, the animal ſeems to feel much pain in the affected heel, which is indicated by his raiſing it frequently from the ground, and his not being able to reſt upon it without uneaſineſs. At this early period, the diſorder may in general be removed by a poultice of boiled bran and linſeed powder conſtantly applied to the part, and kept moiſt with warm water; giving every night, or every ſecond night, a mild diuretic. When the inflammation and ſwelling are conſiderable, the fore-mentioned poultice may be uſed, and a ſtrong diuretic, or a purgative may be adminiſtered as long as the caſe ſeems to require it. When the ſwelling and inflammation have abated, which will commonly happen in three or four days, the poultice may be diſcontinued, and the following aſtringent lotion may be applied five or ſix times a day. Forms of aſtringent lotion, *viz.* No. 1. Alum powdered, 1 oz., vitriolic acid, 1 dr. and water, 1 pint. No. 2. Alum powdered, 4 oz., vitriolated copper, $\frac{1}{2}$ oz., and water, $1\frac{1}{2}$ pint. No. 3. Sugar of lead, 4 oz., vinegar, 6 oz., water, 1 quart. In each of theſe recipes mix the ingredients. Some alteration may be neceſſary, according to circumſtances, in the ſtrength of theſe lotions. Where the inflammation and irritability of the part are conſiderable, they muſt be diluted with an equal quantity of water; but if the inflammation be ſubdued, and a ſwelling and ulceration remain, the alum ſolution cannot be made too ſtrong. If the heels be ulcerated, and eſpecially if they appear foul and have an offenſive ſmell, one or other of the following aſtringent ointments ſhould be applied to the ulcers, *viz.* No. 1. Hog's lard, 4 oz., oil of turpentine, 2 dr., and water of acetated litharge, $\frac{1}{2}$ oz. No. 2. Venice turpentine, 1 oz., hog's lard 4 oz., and alum finely powdered, 1 oz. Mix the reſpective ingredients. If the ulcers be deep, and do not readily heal, they ſhould be waſhed with the detergent lotion previouſly to each dreſſing. Regular exerciſe on clean and dry ground is of the higheſt importance. In ſlight caſes of greaſe, the aſtringent lotion and a few diuretic balls will generally effect a cure; but if the diſeaſe is of long ſtanding, and more eſpecially if the horſe has had it before, it will be more difficult to remove it. In ſuch caſes an alterative powder, compoſed of powdered reſin and nitre of each 4 ounces, mixed and divided into 8 doſes, ſhould be given in the corn every day, until it produces a conſiderable diuretic effect. In very obſtinate caſes, rowels in the thigh have been found uſeful. Digitalis, or fox-glove, has been recommended in thoſe ſwellings of the legs which are the conſequences of greaſe; but as this is a violent medicine, and apt to injure the ſtomach, it ſhould be cautiouſly adminiſtered; the doſe is from half a dram to one dram. When a horſe has ſuffered much from this diſeaſe, and appears to be weak and out of condition, a liberal allowance of corn will tend to recover him, eſpecially if it be aſſiſted by the aſtringent lotion, and careful grooming. In caſes of this kind exerciſe is indiſpenſible. When the diſeaſe depends upon debility it is obvious that a doſe of phyſic would be improper; but conſiderable benefit has ſometimes attended the exhibition every morning, till the bowels are moderately opened, of the following alterative; *viz.* ſoccotrine aloes, 1 oz., caſtile ſoap, $1\frac{1}{2}$ oz. powdered ginger and myrrh, of each $\frac{1}{2}$ oz. Form theſe into a maſs with ſyrup, and divide it into ſix balls. This medicine, though of an opening quality, will improve the horſe's ſtrength, and at the ſame time promote abſorption. Or the following preparation may be adminiſtered: *viz.* antimony, finely powdered, and flowers of ſulphur, of each 6 oz.; linſeed powder, 2 oz.; and honey ſufficient to form a maſs for 12 balls; one of which may be given once or twice a-day.

Nothing tends ſo much to prevent greaſe and ſwelling of the legs as frequent hand-rubbing, and cleaning the heels carefully, as ſoon as a horſe comes in from exerciſe. In inveterate caſes of greaſe, where the diſeaſe appears to be in ſome degree habitual, a run at graſs is the only remedy. If a dry paddock can be procured where the horſe may be ſheltered in bad weather, it will be found very convenient; for thus circumſtanced the horſe may perform his uſual labour, and be kept free from the complaint. In the earlier ſtages of the diſeaſe, the practice of turning the horſe into a ſalt-marſh is ſerviceable: and a few months' run on a ſalt-marſh has frequently eradicated the diſorder, when other remedies have failed. Obſtinate caſes of greaſe may very frequently be cured by withholding the horſe's allowance of water for two days, or even a longer time, and then riding him into the ſea or ſalt water, when his thirſt will induce him to drink freely; and the ſalt water will act as an uſeful laxative and alterative. This proceſs muſt be frequently repeated, whenever it does not appear to be injurious in any material reſpect. In a few obſtinate caſes, Mr. White ſays, (Treatiſe on Veterinary Medicine,) that he has ſeen the mercurial alterative of ſervice, giving one ball every morning, until the bowels are opened: it is formed of calomel, $\frac{1}{2}$ dr., aloes, 1 dr., Caſtile ſoap, 2 dr., and oil of Juniper, 30 drops, made into a ball with ſyrup for one doſe. In the treatment of thoſe ulcers, or "cracks," as they are often termed, which particularly occur in the back part of the paſtern, and which are of difficult cure, cleanlineſs is of great importance; and when they appear inflamed and painful, it will be uſeful to apply a ſoft poultice, in which a little Goulard has been mixed, for two or three days. The following ointment, *viz.* freſh hog's lard, 4 oz. and white lead finely powdered, 1 oz. mixed, may then be applied, ſpread on tow, and ſecured with a light thin bandage. If cracks or ulcers appear in the heels, without that general ſwelling of the legs and diſcharge of matter, which conſtitute the diſeaſe named greaſe, they may be ſoon cured by applying the aſtringent ointment, and giving a few doſes of diuretic alterative: but when theſe are accompanied by the greaſe, laxatives or purgatives are proper, according to the condition of the animal. The aſtringent ointment is made of hog's lard, 4 oz. palm oil, 2 oz. and fine olive oil, 1 oz. melted by placing the pot which contains it in boiling water, and, when melted, ſtirring in $1\frac{1}{2}$ oz. of the water of acetated litharge, and continuing to ſtir it till the mixture is nearly cold. If the ulcers are deep, the horſe ſhould be kept in the ſtable till they are nearly healed, with a cooling opening diet; and his legs ſhould be frequently and briſkly rubbed with the hand; and a few of the diuretic alterative powders ſhould be given. When proud fleſh, as it is called, appears in the ulcers, it muſt be deſtroyed by cauſtics, ſuch as blue vitriol powdered, or diſſolved in warm water, or lunar cauſtic. When this is neglected, they ſometimes increaſe to a large ſize, and become almoſt of a horny conſiſtence, in which ſtate they are commonly named "grapes."

In recent caſes of greaſe, in which the heels are inflamed and ſwollen, and diſcharge a whitiſh-coloured matter, much benefit has reſulted from fomenting them for a conſiderable time with warm water, in which a ſmall quantity of Goulard has been mixed, and immediately applying the Goulard poultice. In obſtinate caſes of greaſe, where the matter diſcharged is very ſolid, the fermenting poultice is uſeful, that is, a poultice of linſeed meal, warm water, and yeaſt, which ſoon removes the offenſive ſmell, and cauſes a leſs acrid matter to be formed. Powdered charcoal has alſo been recommended for the ſame purpoſe. In recent caſes the Goulard poultice and mild purgatives will ſoon reduce the inflammation conſiderably; and then the cure is eaſily accompliſhed by aſtringent lotions. For preventing a return of the complaint, exerciſe and good grooming are indiſpenſably neceſſary; frequent hand rubbing of the legs, and a diuretic powder occaſionally, are alſo uſeful. Horſes with white hinder legs, or ſuch as are much diſpoſed to ſwelling of the legs, ſhould be bandaged for ſome time, particularly after hard work, keeping the bandage conſtantly moiſt with a ſolution of alum and water. In ſome caſes of greaſe the inflammation ſeems to extend to the cellular membrane under the ſkin, the conſequence of which is a more ſevere pain and lameneſs than when it is ſuperficial. The inflammation generally terminates in an abſceſs of the heel, which burſts and leaves a deep ill-looking ulcer. Although the general ſwelling of the legs ſubſides, the ulcer is extremely irritable, and healed with difficulty, particularly if the horſe be exerciſed. By applying poultices and warm digeſtive ointment, and by keeping the horſe at reſt, the ulcer gradually heals. When ulcers of the heel do not appear diſpoſed to heal, the aſtringent ointment above-mentioned ſhould be changed for the following, which is more ſtimulant, and previouſly to its application, the ſore ſhould be waſhed with a ſolution of blue vitriol. The ſtimulating ointment is prepared by mixing ointment of yellow reſin, 4 oz. olive oil ½ oz. and red nitrated quickſilver in fine powder ½ oz. See White's Treatiſe of Veterinary Medicine, vol. i.

If the greaſe be an attendant of ſome other diſeaſe, it will be in vain to attempt the cure before the diſeaſe be removed, that is the original cauſe of it; and therefore, if it be a hectic, the yellows, or the farcin, &c. the directions given for thoſe diſeaſes are to be followed, and in the mean time proper applications are to be uſed outwardly for the greaſe.

GREASE, *Molten*, a diſeaſe of the inteſtines, incident to horſes, and generally dependent on ſome conſtitutional affection. Horſes that have been well fed, without much exerciſe, are peculiarly ſubject to this complaint: although they appear ſleek and fat, they are not fit for violent or long-continued exertion, unleſs they have been brought to it gradually: and therefore when they are put to work in this ſtate, and violently exerciſed, a fever often enſues; and this fever commonly depends upon general inflammation or increaſed action of the whole arterial ſyſtem. In this diſeaſe, nature makes an effort to remove it by a violent purging; and the mucus, formed on the inner ſurface of the bowels for the purpoſe of lubricating and protecting them from the action of any acrimonious matter that may happen to be paſſing through them, being now more abundant, appears ſomewhat like fat mixed with the dung. When blood is drawn from a horſe in this ſtate, a large quantity of inflammatory cruſt, coagulable lymph, or buff-coloured jelly, appears on its ſurface. Such is the account which Mr. White gives of this diſeaſe, and he explodes the account of thoſe veterinary writers who repreſent molten greaſe as conſiſting in a colliquation or general melting of the fat of the body, great part of which is abſorbed, and thrown upon the blood and upon the inteſtines, whence it is voided with the excrement. Nor does he approve of the deſcription of this diſeaſe, given by Mr. Blaine, in his Treatiſe on Veterinary Medicine, who conſiders it to be the ſame with the human dyſentery. In the courſe of a ten years' extenſive practice, he ſays that he has never met with a ſingle caſe that reſembled the dyſentery deſcribed by medical authors. "I have often obſerved," ſays this writer, "during the progreſs of ſymptomatic fever, internal inflammation, mucus mixed with the dung, which had ſometimes the appearance of part of one of thoſe long white worms ſo often found in the horſe's bowels; at others it reſembled a membrane. I have obſerved the ſame thing in horſes apparently healthy, or after the operation of very ſtrong phyſic. I have alſo ſeen many caſes where there was teneſmus or conſiderable irritation in the rectum; the horſe frequently voiding a ſmall quantity of dung, and appearing in pain. But this was always a ſymptom of ſome more important complaint, and eaſily removed, or the effect of phyſic, and very unlike dyſentery." Molten greaſe, according to Mr. White, is not to be conſidered as a diſtinct diſeaſe, but merely as a ſymptom, ſometimes appearing in general inflammation, but more frequently in fevers. In either of theſe caſes ſome of the internal organs are more affected than others. When a difficulty of breathing occurs, indicated by an unuſually quick motion of the flanks and expanſion of the noſtrils, it is a ſign of an affection of the lungs. When molten greaſe appears, it ſhews that the mucous membrane of the bowels is more particularly affected; ſometimes both theſe parts are affected at the ſame time. The principal remedy in this diſeaſe is copious bleeding, according to age, ſtrength, and other circumſtances of the caſe. It is often neceſſary to repeat the operation of bleeding; and if the diſeaſe appears to be principally ſeated in the lungs, only laxatives ſhould be adminiſtered and rowels inſerted in the cheſt and belly; the ſides alſo may be bliſtered, or the muſtard embrocation rubbed on the ſides and belly. In molten greaſe, or when the bowels are affected, if a copious purging occurs, it ſhould not be ſuppreſſed, but encouraged, by giving frequent decoctions of linſeed, gum arabic diſſolved in water, ſtarch, or the powder of arrow root, and boiled in water. When the dung is voided ſparingly, but frequently, and particularly when any knobs are mixed with it, let a pint of caſtor oil be given, which may be repeated, if neceſſary, about two days. In this caſe it will be proper to rub the muſtard embrocation on the belly. If the diſeaſe continue, and eſpecially if there be conſiderable irritation about the anus; the horſe frequently ejecting a ſmall quantity of excrement, and appearing to be in great pain, the following opiate clyſter may be given, *viz.* opium 1½ dram, warm water 8 oz. mixed, to which add about a quart of ſtarch water, *i. e.* ſtarch boiled in water, of a proper conſiſtence for a clyſter. If the exhibition of a clyſter ſeems rather to increaſe than alleviate the pain and irritation, the doſe of caſtor oil muſt be repeated, and a clyſter thrown up only of water, gruel or a little oil. As the gut in this caſe is very tender and irritable, the clyſter pipe ſhould not be rough, and it ſhould be introduced with caution; it ſhould therefore be perfectly ſmooth, covered with oil or lard, and not protruded with violence. It is probable, ſays Mr. White, that a ſmall, ſhort tube of bone, about three times the bulk and length of the pipe uſed in human ſubjects, would be preferable on this occaſion to that which is commonly employed. White's Treatiſe of Veterinary Medicine, vol. i.

GREASE, among *Hunters*, denotes the fat of a bear or hare.

GREASY, in *Agriculture*, a term provincially made uſe of to imply any thing foul, whether in animals or land. It is frequently uſed to ſignify ſuch tillage lands as are much over-run with graſs when in the ſtate of fallow.

GREASY-*Blaes*, or *Creechy-blaes*, in *Mining*, are terms by which kind ſhale or ſlate clay, or that which has a greaſy appearance, and works or digs eaſily, is diſtinguiſhed. See SHALE.

GREAT, a term of compariſon, denoting a thing to have more extenſion than ſome other to which it is referred. Thus we ſay, a great ſpace; a great diſtance; a great figure, a great body, &c. See COMPARISON.

GREAT is likewiſe uſed figuratively, in matters of morality, &c. to ſignify ample, noble, elevated, extraordinary, important, &c. Thus we ſay, Shakſpeare was a great genius; queen Elizabeth had a great ſoul; Cromwell was a man of great deſigns; Da Vinci, a great painter; Galileo, a great philoſopher; Boſſu, a great critic, &c.

GREAT is alſo a title or quality appropriated to certain princes, and other illuſtrious perſonages. Thus we ſay the great Turk; the great Mogul; the great khan of Tartary; the great duke of Florence, &c.

GREAT is alſo a ſurname beſtowed on ſeveral kings and emperors. Thus we ſay, Alexander the great, Cyrus the great; Charles the great, or Charlemagne; Henry the great of France, &c. So the Engliſh frequently ſay, Edward the great, or the great Edward; William the great, meaning king William III. or the great William. The French ſay Louis the great, *le grand*, ſpeaking of Louis XIV. Giles of Paris ſays, Charlemagne firſt got the ſurname great from the tallneſs and eminence of his ſtature. Helgaud adds, that Hugh the great of France was thus denominated on account of his great piety, goodneſs, &c.

GREAT is alſo applied to ſeveral officers who have preeminence over others. Thus we ſay, the lord great chamberlain; the great marſhal of Poland, &c.

GREAT *Circles of the ſphere*. See *Great* CIRCLE.

GREAT *Circle ſailing*. See SAILING.

GREAT *Apparatus*. See APPARATUS.

GREAT *Artery*. See ARTERY.

GREAT *Bairam*. See BAIRAM.

GREAT *Bank of Newfoundland*, in *Geography*. See BANK. It lies between 41° and 50° 24′ N. lat., and between 49° 45′, and 54° 45′ W. long.

GREAT *Barrington*. See BARRINGTON. The number of inhabitants by a late eſtimate is 1754.

GREAT *Bay*, a bay of North America, at the mouth of the Piſcataqua river, between Portſmouth and Exeter, in the ſtate of New Hampſhire.

GREAT *Bear lake*. See BEAR *lake*.

GREAT *Bear*. See URSA *major*.

GREAT *Cape*, in *Geography*, a Cape of Upper Canada, where lake Superior deſcends into the narrows of the fall St. Mary.

GREAT *Diachylon*. See DIACHYLON.

GREAT *Egg harbour*, &c. in *Geography*. See EGG *harbour river*.

GREAT *Famine*, a river of America, in New York, which riſes in the mountains near the ſource of the river Oneida, and runs N. W. by W. to lake Ontario.

GREAT *Gun*. See CANNON and GUN.

GREAT *Intervals*, in *Muſic*, ſignify the ſame, with Holden and ſome other writers, as greater and major do with the generality of muſicians, and is applied to the intervals marked with Roman capitals, as II, III, V, VI, VII, &c. See GREATER.

GREAT *Iſland*, in *Geography*, a ſmall iſland in the Eaſt Indian ſea, near the N. coaſt of the iſland of Flores. S. lat. 7° 59′. E. long. 120° 54′.—Alſo, an iſland in the river Niagara, between lake Erie and lake Ontario. N. lat. 53°. W. long. 78° 59′.—Alſo, an iſland of Ireland, in the county of Cork, being the largeſt of the iſlands formed by the river Lee in Cork harbour; on it is the flouriſhing town of Cove.—Alſo, an iſland in Piſcataqua harbour, New Hampſhire, in the United States.

GREAT *Kanhaway*. See KANHAWAY.

GREAT *Letters*. See CAPITALS.

GREAT *Maſs*. See MASS.

GREAT *Mecatina*. See MECATINA.

GREAT *Octave*, in *Muſic*, is applied by the Germans, according to their tablature, or notation of muſical notes, to the octave, or rather ſeptave, beginning with C on the ſecond leger line below the baſs ſtave, and ending with B on the ſecond line, or *mi* of Guido, and to which they excluſively apply the Roman capitals C, D, E, F, G, A, B. See Dr. Callcott's Muſical Grammar, art. 34. See alſo SMALL OCTAVE, ONCE-MARKED *Octave*, and TWICE-MARKED *Octave*.

The object of this tablature is, to enable muſical notes to be written or printed without clefs or lines and ſpaces in a ſtave.

GREAT *Officers*. See OFFICER.

GREAT *Pelican Iſland*. See PELICAN.

GREAT *Repeat*. See REPEAT.

GREAT *Ridge*, in *Geography*, one of the ridges of the Alleghany mountains, which ſeparates the waters of the Savannah and Alatamaha. At the S.E. promontory of this ridge is that extraordinary place called Buffaloe lick, diſtant about 80 miles from Auguſta. It occupies ſeveral acres of ground. A large cane ſwamp and meadows, forming an immenſe plain, lie S.E. of it, and in this ſwamp Mr. Bartram apprehends that the branches of the great Ogechee take their riſe. The lick is nearly level, and lies between the head of the cane ſwamp and the aſcent of the ridge.

GREAT *River*, a river of Virginia, which runs into the Staunton river. N. lat. 36° 46′. W. long. 79° 12′.—Alſo, a river of Canada, which runs into the river St. Lawrence, 20 miles below Quebec.

GREAT *River*. See RIO *Grande*.

GREAT *Scale*, in *Muſic*. The late ſir Marmaduke Overend, after a life almoſt ſpent in reſearches into the nature and proportion of muſical intervals, ſucceeded, to the ſatisfaction of Dr. Boyce, his intimate friend, to whom his labours were ſubmitted, in unravelling the myſteries of the Greek ſcales of muſic, as he ſays, in a paper on the great ſcale, in his quarto manuſcripts, vol. ii. page 113 to 133, now in the library of the Royal Inſtitution, which is thus entitled, *viz.* "All the Greek ſcales of muſic combined, with the diatonic intenſe, extended in the acumen and gravitas, with their remiſſions and intenſions to double flats and double ſharps in each; firſt reſtored, elucidated, and calculated, by Marmaduke Overend, Iſleworth 1779." In pages 143 to 149 of the ſame volume of MS. we find alſo the ſeveral ratios of this ſcale in their leaſt terms, and the indices of the component primes, of one octave of the acumen and the gravitas with the ſynemmenons, the remiſſions, &c. This ſcale, which contains 86 notes within the octave, is a great muſical curioſity, which we are ſorry that our limits will not admit of inſerting: by the notice here taken of it, the curious may reſort to the manuſcripts themſelves for further ſatisfaction. See *Greek* SCALE.

GREAT *Seal*. See SEAL.

GREAT *Sixth, Redundant*, in *Muſic*, or redundant great ſixth, according to Holden, is the inverſion of the deficient leſs third of his ſcales ($\frac{6}{7}$), and has a ratio of $\frac{7}{12}$, $= 475.94709\,\Sigma + 9f + 41\,m$ in Farey's notation, its common logarithm being .7659167.9396, its Euler's log. or decimal of the octave = .7776075, and it contains 43.38868 major commas. This interval does not belong to the received or diatonic ſyſtem, having the number 7 in its ratio.

GREAT *Sodus*. See SODUS.

GREAT *Third*, in *Muſic*, probable, according to Holden's new and fanciful ſyſtem, is the ratio which the mind "probably" conceives (page 371 of his "Eſſay") as pertaining to the major third in the common chord minor, and to which he aſſigns the numbers $\frac{19}{24}$, $= 206.270982\,\Sigma + 4f + 18\,m$ in the new notation: its common logarithm is .8985423 5924 and that of Euler, .3570350, it alſo contains 18.80576 major commas; it is far removed from the received or diatonic ſyſtem of intervals, as involving the prime number 19, and yet it is one of thoſe which reſult from earl Stanhope's directions for tuning; it is the leſſer equal-beating biequal third of his lordſhip, ſee EQUAL BEATING. Mr. Holden, at page 384 of his eſſay, relates an experiment in which this third proved an "intolerable diſcord," which is more than might be expected, from the temperament of rather more than $\frac{9}{11}$ths of a comma, which it has.

GREAT *Tithes*. See TITHES.

GREAT *Wardrobe*. See WARDROBE.

GREAT *Wheel*, in *Clock* or *Watch-work*, is that wheel which the weight, ſpring, or fuſee, firſt moves.

GREAT *Work*, in *Chemiſtry*, is the alchemical proceſs whereby gold is made, or pretended to be made.

GREAT *Year*. See PLATONIC *year*.

GREATER *Barons*. See BARON.

GREATER *Enharmonical dieſis*. See DIESIS.

GREATER *Excommunication*. See EXCOMMUNICATION.

GREATER *Faſti*. See FASTI.

GREATER *Hexachord*. See HEXACHORD.

GREATER, in *Muſic*, is applied to diſtinguiſh ſeveral intervals, whereof there are two of the ſame name, as greater ſecond, leſſer ſecond; greater third, leſſer third; &c. Major interval is as often applied to theſe, and by ſome few writers they are called great intervals. The ſemitone or difference between the *greater* and the *leſſer* intervals of the ſame names, are not all equal, but of two different magnitudes, *viz.* the ſemitone minor ($\frac{24}{25} = 36\,\Sigma + f + 3\,m$), which occurs between the thirds and the ſixths major and minor, and the ſemitone medius ($\frac{128}{135} = 47\,\Sigma + f + 4\,m$), which occurs between the ſeconds, fourths, fifths, and ſevenths, major and minor: the difference of theſe ſemitones being the major comma $\frac{80}{81} = 11\,\Sigma + m$.

GREATHAM FLEET, in *Geography*, a river of England, which riſes in the county of Durham, and runs into the German ſea, 5 miles S. of Hartlepool. N. lat. 54° 43′.

GREATMAN'S BAY, a bay of Ireland, on the N. coaſt of Galway bay; ſix miles N. from S. Arran iſles.

GREAVES, JOHN, in *Biography*, was born at Colmore, near Alresford, in Hampſhire, in the year 1602. He was educated in the claſſics, and in the other elementary parts of learning by his father, who was rector of the place, and the moſt celebrated ſchool-maſter in that country. When he was fifteen he was ſent to Baliol college, Oxford, where he applied himſelf with great aſſiduity to the ſtudies of the place, and took his firſt degree in the year 1621. Three years after this he ſtood candidate for a fellowſhip of Merton college, when he was the firſt on the liſt of five who were then elected. In 1628 he took the degree of M.A., and more particularly directed his attention to the ſtudy of the mathematics and oriental learning, and became the friend of the moſt eminent ſcholars in the univerſity, among whom were Mr. Briggs, Savilian profeſſor of aſtronomy, and Mr. Peter Turner, profeſſor of geometry in Greſham college, London. Had he wanted any motive to induce him to purſue his ſtudies with vigour, the example of his contemporaries would have furniſhed that motive. Mr. Greaves read over all the writings of the moſt celebrated mathematicians of that and the preceding age, and he made himſelf familiar with the ancient Greek, Arabian, and Perſian authors. In the year 1630, upon the reſignation of Mr. Turner, he was elected profeſſor of geometry at Greſham college, in conſequence of the high reputation which he ſuſtained in the univerſity. At this period he was introduced to archbiſhop Laud, the chancellor of the univerſity of Oxford, from whom he received ſeveral marks of favour. Soon after this, Mr. Greaves reſolved to travel for improvement, and in 1635 we find him in Holland, attending the lectures of James Golius, profeſſor of Arabic at Leyden; from thence he proceeded to Paris; afterwards to Rome, Florence, and Padua, making exact obſervations upon every thing deſerving of notice. Upon his return he determined to take a voyage to Egypt, a deſign which met with the decided approbation of the archbiſhop. His object in this was not only to make himſelf acquainted with ſuch remains of antiquity which that far-famed country poſſeſſed as might ſerve to illuſtrate ancient literature, but alſo to make aſtronomical and geographical obſervations; he therefore furniſhed himſelf with inſtruments of every kind for the purpoſe, and ſuch printed Greek and Arabic books as he thought might be advantageouſly exchanged for MSS. and other objects worthy of collection. He embarked in the river Thames for Leghorn in the year 1637, accompanied by his friend Mr. Edward Pococke, and proceeded firſt to Italy, and thence to Conſtantinople, where they arrived about Michaelmas. Here he was received with great attention by ſir Peter Wyche, to whom he brought out letters of recommendation from archbiſhop Laud. He was immediately introduced to Cyril Lucar, the Greek patriarch, who afforded him much valuable aſſiſtance in purchaſing Greek MSS. The venerable patriarch promiſed to recommend him to the monks of mount Athos, in Macedonia, where, he ſaid, "he would have had the liberty of entering all the libraries in that place, to have collected a catalogue of ſuch books, as either were not printed, or elſe, by the help of ſome, theſe might have been more correctly ſet out." Theſe, by diſpenſing with the anathemas which former patriarchs had lain upon all Greek libraries to preſerve the books from the Latins, the patriarch propoſed to have preſented to the archbiſhop of Canterbury, for the better proſecution of his grace's deſigns in the edition of Greek authors, but the death of that patriarch fruſtrated Mr. Greaves' intention of viſiting the celebrated mount, and occaſioned his being a ſufferer in another reſpect; for having procured from a Greek monaſtery ſome MSS. of the fathers, he was under the neceſſity of reſtoring them, and loſing his money to avoid a greater inconvenience. Mr. Greaves, having loſt his friend, determined to proceed to Egypt, but before his departure he had an opportunity of ſhewing his great attention to aſtronomical ſcience: knowing that there would be an eclipſe of the moon in the courſe of a few months, he furniſhed proper perſons with convenient inſtruments for obſerving it at Conſtantinople, Bagdad, Smyrna, and Alexandria, and gave them neceſſary inſtructions for the purpoſe. For his conduct in this reſpect Dr. Halley paid him the higheſt compliment by ſaying that a greater ſervice could not be rendered to the ſcience of aſtronomy than by taking the phaſes of the moon's eclipſes at thoſe places, in order to determine their longitudes, ſince in and near them were made all the obſervations by which the mean motions of the ſun are limited. Mr. Greaves having finiſhed his arrangements for this buſineſs, went by Rhodes to Egypt, and arrived there in the month of September 1638. This was the boundary of his intended journey, and here an immenſe field for the exerciſe of his inquiſitive genius opened upon his view. He omitted no opportunity of examining whatever the heavens, the earth, or ſubterraneous parts offered him, that might be deſerving of notice; but complains of having his aſtronomical obſervations frequently interrupted by the clouds and rain, which he found to be frequent, eſpecially in the middle of winter. But what particularly engaged his attention, and employed his care, were the pyramids, of which, at that time, there was no ſatisfactory account before the public. This taſk he undertook, and towards the cloſe of the year 1638 he took a careful ſurvey and menſuration of them. Having gratified his curioſity, furniſhed his mind with a large ſtock of uſeful knowledge, and collected ſome Greek, Arabic, and Perſian MSS., as well as ancient coins, and other varieties, he embarked at Alexandria in the month of April 1639, and arrived at Leghorn in June. He now made a ſecond tour of Italy, which occupied him nine months. At Florence he was received with particular marks of reſpect by the grand-duke of Tuſcany, Ferdinand II., to whom he addreſſed a Latin poem ſent from Alexandria; and he alſo was permitted to have free acceſs to the Medicean library, which had been refuſed to him as a ſtranger when on his former tour. From Florence he went to Rome, whence he returned to Leghorn, and embarked on board a veſſel for London, with a rich cargo of MSS., gems, coins, and other valuable antiquities. Upon his arrival in England he found his native country diſtracted by the conteſts between the king and parliament: he was, from principle, a friend to the royal party, and involved himſelf in much trouble by the zeal which he diſplayed in the cauſe of monarchy, and in his attachment to archbiſhop Laud. Having made a ſhort ſtay at Greſham college, he went to Oxford to digeſt and prepare his papers for publication, in which he was aſſiſted by archbiſhop Uſher, who had long known and eſteemed him; and he now drew a map of the Leſſer Aſia, at his grace's requeſt, who was writing his diſſertation on that country, which was printed in 1641. In this year archbiſhop Laud having preſented to the univerſity a ſecond collection of medals, the taſk of arranging them was confided to Mr. Greaves, which he performed to the entire ſatisfaction of that learned prelate. By continuing to reſide ſo long at Oxford, Mr. Greaves loſt his profeſſorſhip at Greſham college, but he was almoſt at the ſame time choſen the Savilian profeſſor of aſtronomy at Oxford, and obtained likewiſe a royal diſpenſation to hold his fellowſhip at Merton college, on account of the diminution in his ſtipend as profeſſor, ariſing from the circumſtances of the civil war. The labours of the profeſſorſhip being ſuſpended, he proceeded with his literary avocations, and in the year 1644 tranſlated into Latin the “Lemmata of Archimedes,” correcting the diagrams, and ſupplying what was frequently found defective in the demonſtration itſelf. This piece was publiſhed by Mr. Samuel Foſter in his Miſcellanies, or “Mathematical Lucubrations,” 1659. Mr. Greaves, about the ſame time, compiled “A Perſian Lexicon,” out of ſuch words as could be met with in the evangeliſts, the pſalms, and two or three Arabian and Perſian nomenclators. In 1645 he drew up a ſcheme for gradually introducing the new or Gregorian ſtyle, by omitting the intercalary day of the leap-year for forty years, which ſcheme was highly approved by the king and council, and would probably have been carried into execution, had the times been favourable to the innovation. In 1646 he publiſhed his work entitled “Pyramidographia,” or a deſcription of the pyramids of Egypt, and ſoon after a “Diſcourſe on the Roman Foot and Denarius,” from whence, as from a common ſtandard, the meaſures and weights uſed by the ancients may be deduced. About the year 1648 Mr. Greaves found that he ſhould be under the neceſſity of reſigning his profeſſorſhip, he accordingly, before his intereſt was entirely gone, introduced a ſucceſſor, *viz.* Mr. Seth Ward, afterwards biſhop of Saliſbury. He then went to London, where he married, and living upon his patrimony, devoted his time to literary labours. He publiſhed many learned works, among which was “Elementa Linguæ Perſicæ,” 4to. to which the author ſubjoined “Anonymus Perſa Siglis Arabum et Perſarum Aſtronomicis.” In 1652 he publiſhed an aſtronomical work, to which he prefixed “A ſhort Hiſtory of the Riſe and Progreſs of Aſtronomy among the Arabians,” and ſubjoined his Binæ Tabulæ. Beſides theſe, he publiſhed many other works, and had prepared many more for the preſs, when he was attacked by a diſorder that proved fatal to him. He died in the fiftieth year of his age. Of his learning, ingenuity, diligence, and wonderful perſeverance, there is abundant evidence. He was highly eſteemed by many of his moſt eminent contemporaries both at home and abroad; ſteady in his principles and in his friendſhips, and his death was lamented as a real loſs to ſcience and literature. Biog. Brit.

GREBANISH HEAD, in *Geography*, a cape of Scotland, on the E. coaſt of the peninſula of Harris. N. lat. 57° 48′. W. long 6° 43′.

GREBE, in *Ornithology*, is claſſed by Linnæus under the genus of *Colymbus*, which ſee.

GREBENSKOI. See COSSACKS.

GREBENSTEIN, a town of Heſſe-Caſſel, 12 miles N.W. of Caſſel. N. lat. 51° 26′. E. long. 9° 22′.

GREBER, GIACOMO, in *Biography*, a German muſician, who had been ſome time in Italy, and who brought hither a female ſinger, his ſcholar, la ſigniora Margarita de l'Eſſine. He ſet to muſic a paſtoral entertainment, entitled “The Loves of Ergaſto,” after the manner of the Italian opera, that is, in recitative, with airs intermixed. This was the firſt performance in ſir John Vanburgh's new theatre in the Haymarket, afterwards called the Opera Houſe. Greber's ſcholar, Margarita, ſung in moſt of the early attempts at operas in England, and from the name of her maſter, Greber, was long called “Greber's Peg;” which occaſioned his name to be better known, and longer remembered than his works. See MARGARITA.

GRECI, in *Geography*, a town of Naples, in the province of Principato Ultra, founded by a colony of Albanians, who left their country after their prince George Caſtriot, near Ariano.

GRECOURT, JOHN-BAPTIST JOSEPH VILLART DE, in *Biography*, was born at Tours, in France, in 1683. He was devoted by his friends to the church at a very early period, and was in poſſeſſion of a canonry when he was only fourteen years of age. He became celebrated as a preacher, but his diſcourſes were ſatirical rather than moral, and did not redound much to his credit as a preacher of the goſpel. Quitting his profeſſion he became a man of the world, and made his way to the faſhionable circles by his convivial talents, and his faculties of writing and reciting licentious and burleſque verſes. He was patronized by the marſhal duke d'Etrees, who frequently carried him to his ſeat, which the poet called his earthly paradiſe. The life which he led would not bear reflection; and though he apparently ſpent a joyous courſe, yet there was a ſmall portion of reſpectability attached to his character. He died in 1743. His printed works were tales, epigrams, ſongs, fables, and other light pieces. Few of them riſe above mediocrity, but they are lively, pleaſant, and popular. His poem, entitled “Philotanus,” which was a ſatirical hiſtory of the bull Unigenitus, had prodigious ſucceſs. The verſes are burleſque, ſome of them extremely humorous, though their general texture is mean and vulgar. Moreri.

GREDING, in *Geography*, a town of Germany, in the principality of Aichſtatt, on the Schwarzach; 13 miles N.E. of Aichſtatt.

GREE, a town of Perſia, in Segeſtan; 20 miles S.W. of Meimend.

GREE, in our *Law Books*, ſignifies agreement, contentment, or good liking. Thus, to make *gree* to the parties, is to ſatisfy them for offence done. “Judgment ſhall be put in ſuſpence, till *gree* be made to the king of his debt.” Stat. 25 Edward III.

The word is formed from the French *gré*, *good will*, *good liking*, or *allowance*.

GREECE, in *Geography*, a country of Europe, ſubject to the Turks, and more generally known under the name of *Turkey in Europe*, which ſee.

GREECE, in *Ancient Geography*. See GRÆCIA.

GREEK *Accents*. See ACCENT.

GREEK *Bible*. See BIBLE.

GREEK *Church*. See CHURCH

GREEK *Church, Muſic of the*. The ſchiſm between the Greek and Roman churches, which happened in the ninth century, prevented ſuch changes as were made in the Roman ritual, after that period, from being adopted by the Greeks; and the notation uſed before ſeems long to have continued in the Eaſt. In Ruſſia, however, all the rituals were called in at the beginning of the laſt century; and a uniform liturgy was eſtabliſhed, in which the modern method of writing muſic was received. But in the Greek iſles a notation peculiar to its inhabitants is ſtill in uſe, which is not only as different from our's as their alphabet, but totally unlike that in the ancient miſſals.

In examining the moſt ancient of theſe in the Vatican library, which were written in capitals, the firſt notation which we could diſcover, conſiſted chiefly of accents; and when ſmall letters were afterwards uſed, theſe accents were only ſomewhat lengthened. In the tenth and eleventh centuries, they very much reſemble the characters to be found in contemporary Latin miſſals. However, the melodies in the lower ages became more elaborate, and the notes more numerous than in thoſe of higher antiquity.

St. John Damaſcenus, who lived in the eighth century, is celebrated by the writers of his life, and by eccleſiaſtical hiſtorians, as the compiler and reformer of chants in the Greek church, in the ſame manner as St. Gregory in the Roman. And Leo Allatius (De Libris Eccleſ. Græcorum) under the title "Octoëchus" (Οκτωηχος; eight tones), tells us they were compoſed by J. Damaſcenus. Zarlino goes ſtill farther, and informs us (Inſtit. Harm. 4to. parte. cap. viii.) that in the firſt ages of Chriſtianity the ancient Greek notation by letters having been thrown aſide, John Damaſcenus invented new characters, which he accommodated to the Greek eccleſiaſtical tones; and that theſe characters did not, like our's, merely expreſs ſingle ſounds, but all the intervals uſed in melody; as a ſemitone, tone, third minor, third major, &c. aſcending and deſcending, with their different duration. This reſembles, in many particulars, the notation in the eccleſiaſtical books of the Romiſh church, before the time-table, and characters in preſent uſe were invented, or, at leaſt, generally received.

The abate Martini of Venice (ſee "Preſent State of Muſic in France and Italy") having viſited the Greek iſles in hopes of acquiring ſuch a knowledge of the muſic practiſed there at preſent, as would enable him to judge whether any of the miraculous powers attributed to it by their anceſtors ſtill remained, as well as to compare its excellence with that of his own country; and as this learned and ſagacious enquirer confided to us his papers on that ſubject, we ſhall communicate to our readers a ſketch of their contents.

The ſyſtem of modern Greek notation ſeems much more complicated and obſcure than the ancient. The characters convey nothing to the mind either by their form or names, the greateſt part of which cannot be conſtrued; and the reſt are conſtrued to no purpoſe. Their ſignification, as words, does not point out their meaning as muſical characters; and all that we can diſcover is, that ſome of them ſeem deſcriptive of geſticulations; ſuch as ἐρχνισμα, which, perhaps, directed the prieſt to look up, or ſtretch his hands towards heaven. Σταυρος, which might direct him to make the ſign of the croſs, or to carry the croſs. Λυγισμα, *flexio, contortio.* Indeed, it is ſaid in the papers, that ſome of theſe characters are for the Χειρονομια, or *legerdemain*, and not δια φωνην, for the *voice*. This is the more likely, as the Greek ſervice abounds in geſticulations and manual dexterity.

The abate was informed, that though the oriental Greeks have ſigns for muſical ſounds equivalent to our's, they ſing more by tradition than ſcience. However, the diſtinctions for the duration of ſounds, ſuch as our time-table furniſhes, are ſtill wanting. The abate procured an extract from a tract upon the muſic of the modern Greeks, written by Lampadarius; but who he was, or when he lived, no one could inform him. In this it appears, that the characters amount to more than fifty; among which moſt of the names of thoſe muſical terms, given by Du Cange, from a MS. treatiſe on the eccleſiaſtical muſic of the Greeks, are to be found. (Gloſſ. Med. et Inf. Græcitatis.) Du Cange, who has ſo amply collected and explained the characters uſed by the modern Greeks in chemiſtry, botany, aſtronomy, and other arts and ſciences, is ſilent as to their muſical notation; nor have we been able to acquire any information on that ſubject, except that with which the abate Martini has ſupplied us. The title of the treatiſe by Lampadarius is the following: Τεχνολογια της μουσικης τεχνης. The extract from it, which is in our poſſeſſion, is too long for inſertion here; nor would it be of much uſe could we allow it room, as no equivalents to the Greek characters are to be found in our own notation. But with reſpect to the author, we find among the memoranda which we made in the king of Sardinia's library at Turin, an account of a Greek MS. of the fifteenth century, N. 353. b. I. 24, in which Lampadarius is often mentioned as author of the muſic to the hymns and prayers it contains. Fabricius likewiſe, Bibl. Græc. vol. ii. p. 269, 564, and 586 ſpeaks of a MS. in the Selden collection at Oxford, and another in the Jeſuits library at Louvain, in which there are explanations of the notes uſed by the modern Greeks, and muſical compoſitions by ſeveral authors, particularly Lampadarius. In the patriarchal church of Conſtantinople there are four ſingers, who are placed on the right and left ſides of the choir; the firſt on the right is called Πρωτοψάλτης, the principal ſinger; the firſt on the left Λαμπαδαριος, Lampadarius; the two others who aſſiſt the principals are called *domeſtici.* It is probable that Lampadarius, who flouriſhed about the year 1300, either took his name from the office he filled; or, on account of his eminence in muſic, that his name was given to the office.

To inſert here the muſical characters ſtill uſed in the rituals of the Greek church out of Ruſſia, and endeavour to explain them, will perhaps be conferring but a ſmall favour on our readers; for from the ſcarcity of muſic written in ſuch characters, ſo few will be their opportunities of making uſe of any knowledge they may acquire by the ſtudy of them, that it would be like learning a dead language in which there are no books, or a living language without the hopes of either reading or converſing in it.

Thoſe readers who may be deſirous of gratifying themſelves in matters of curioſity, may conſult Dr. Burney's Hiſtory of Muſic, vol. ii. p. 50. where they will find the fourteen muſical characters that occur in the Greek MSS of the Evangeliſts, written in capitals during the ſeventh, eighth, and ninth centuries, though at preſent they are wholly unintelligible, even to the Greeks themſelves. It is obſervable that the more ancient the MSS. the fewer and more ſimple are the notes: the "Codex Alexandrinus," in the Britiſh Muſeum has none; and the Evangeliſteriæ MSS. in the Harleian collection, 5785, 5598, both of the tenth century, have only ſuch as theſe, which were copied in Greece by the abate Martini.

The "Codex Ephrem," in the king's library at Paris, of the fifth century, has likewiſe the ſame kind of muſical notes, and it is aſſigned as a reaſon for the "Codex Alexandrinus" not having them, that it was written for private uſe, not for the ſervice of the church.

Kircher undertakes to give his reader an idea of modern Greek muſic and its characters; and has indeed collected a great number of notes and their names, but pretends not to furniſh equivalents in the muſic of the weſtern world. And to inſert ſuch barbarous names, and more barbarous characters here without explanation, would no more help to initiate a ſtudent in the myſteries of Greek muſic, than the Hebrew or Chineſe alphabet. At the firſt glance they very much reſemble the characters uſed in Choregraphy, an art invented about two hundred years ago to delineate the figures and ſteps of dances. They are too numerous and complicated to be inſerted and explained here; however, we have given the names and correſpondent notes in the Hiſtory of Muſic, vol. ii. p. 51 – 52, by the ſtudy of which the muſical reader will be able to form ſome idea of the melody which they are intended to expreſs.

There are eight aſcending, and ſix deſcending characters, ſome for ſingle ſounds, and others for wider intervals, as thirds and fifths, ſuch as Zarlino, in the paſſage mentioned above, had imagined were invented by J. Damaſcenus; and all theſe have their particular *Chironomia*, or ſigns for the geſtures with which the prieſt is to accompany the inflections of voice.

The beginning, or firſt note of every chant, is called *Iſon*, which is equivalent to the key or tone in which any melody is ſung.

Kircher, to whom even Egyptian hieroglyphics are eaſy, has reſolved the names of theſe Greek notes into Latin. Muſurgia, ubi ſupra.

The abate Martini heard the Greeks, in Paſſion Week, ſing ſeveral tropes or modes, which they now term ηχοι, in four parts, in the ſtyle of Paleſtrina: and this kind of muſic they call Cretan, but why, is not eaſy to divine, unleſs they learned counterpoint while the Venetians were maſters of the iſland.

The abate ſays that he often heard the common people of Greece ſing in concert, and obſerved that they made frequent uſe of the *fourth*: "della conſonanza che noi chiamiamo oggi quarta." By this he muſt mean that they uſed it as a concord in two parts, or if there were more than two parts, in poſitions where our harmony forbids the uſe of it; otherwiſe it would not have affected his ear as a ſingularity.

The fact is curious, and we find it confirmed by Zarlino, who obſerved the ſame practice in the Greek church at Venice. The fourth, we find, was in ſuch favour during the time of Guido, as to be preferred in diſcant to every other concord, and thought to conſtitute the moſt pleaſing harmony. This partiality may probably have ariſen from the importance of fourths in the ancient Greek ſyſtem, and the want of a temperament to render thirds and ſixths more agreeable; but the improvements in harmony ſoon brought it into diſgrace in Italy, while, from a contrary cauſe, it has kept its ground to the preſent time in Greece, at leaſt among the populace. And, indeed, even in Italy, it ſeems to have retained a part of its ancient privileges long after the time of Guido, and when harmony was thought to be in great perfection: for Zarlino ſays, that Juſquin, and the other old Flemiſh maſters, uſed it frequently in their compoſitions: "nella parte grave, ſenza aggiungerle altro intervallo."

The preſent ſtate of Greek muſic, indeed, does not confirm or favour the opinion of Dr. Brown, who aſſerts with his uſual courage, that, "about four hundred years after Guido, the debauched art once more paſſed over into Italy from Greece: certain Greeks, who eſcaped from the taking of Conſtantinople, brought a refined and enervate ſpecies of muſic to Rome, &c." As many travellers aſſert that the modern Greeks have no muſic in parts, we may ſuppoſe, that in thoſe places where it was heard by the abate Martini, it had been brought thither by the Venetians, during the time that they had poſſeſſions in the Archipelago.

That the Greek muſic has undergone many alterations ſince the ancient treatiſes that are come down to us were written, is certain from the change and increaſe of its vocabulary. Bryennius has given, as names of intervals, a liſt of barbarous terms not to be found in any preceding writer within our knowledge; and in the Greek gloſſary of Du Cange, and the abate Martini's papers, a great number occur that are not to be found either in writers of high antiquity, or in Bryennius.

The technical language of the Greeks has always been copious, and in muſic perhaps its ſeeming redundance is more conſpicuous than in any other art or ſcience. But in other arts and ſciences words are repreſentatives of things exiſting; whereas, in denominating the tones and inflexions of voice, which, to realize, require new creation, there can be no correſpondence between the type and ſubſtance. The colours, the forms, and objects, which a painter wiſhes to repreſent, are in nature; and the poet, in all the ebullition of wild enthuſiaſm and fervid imagination, deſcribes what he has ſeen and felt, or what *is* to be ſeen and felt, and for which common language muſt ſupply him with ſymbols. But it has never entered the thoughts of man to give names to all the minute ſhades of colour between black and white, or to the gradations by which light is propagated between the time of total darkneſs and the ſun's meridian. And yet, in a ſcale of ſounds, from the loweſt muſical note in the human voice to the higheſt, where octaves are not repreſented by ſimilar ſigns and appellatives, the names and characters muſt be numerous. The lines and clefs of the European muſic have certainly freed it from many perplexities with which it was embarraſſed, even in the artleſs times of canto fermo.

But however flowery the Greeks may have made their eccleſiaſtical melody, or however they have multiplied its characters, the deſire of permanence in the heads of the weſtern church, with reſpect to all ſacred matters, long kept muſic in the plain and ſimple ſtate in which it was left by pope Gregory the Great; for we do not find, till the invention of counterpoint, that it received any material change or improvement. Our own bible and liturgy, if they remain in their preſent ſtate five or ſix hundred years, will, perhaps, be unintelligible to the vulgar, though written in the beſt language of this country when they were introduced into the church. And the Greek and Roman languages, which were ſo well underſtood by the primitive Chriſtians, became dead and obſolete by degrees, to all but the learned in after ages. The precluſion of change or innovation in ſacred concerns which has occaſioned permanence, has likewiſe been the cauſe of inelegance and obſcurity.

"Peter the Great, like his predeceſſors, had a particular partiality for the muſic of the church; maintained his own choir, or ſingers for divine ſervice, and read publicly in the church the epiſtles and the hours, which, in that country, is permitted to be done by any layman, who delights in ſuch exerciſe, as well as by the prieſts." (King's Rites of the Greek Church.)

Many of the kings of France not only ſung in the choir, but compoſed hymns for it, and ſet them to muſic. (Laborde.)

(Laborde.) And we have heard his preſent majeſty, at ſix o'clock prayers in St. George's chapel at Windſor, officiate alone as clerk ; repeating the reſponſes, and reading the pſalms aloud verſe for verſe, with the miniſter, and uttering the amen in the clerical ſtyle.

Muſic has been very much cultivated at Peterſburgh in the Imperial chapel and metropolitan church during the laſt century, as well as in the theatre. And though no inſtruments are admitted in the Greek church, any more than in the Siſtine or pontifical chapel at Rome, yet every vocal refinement, both in compoſition and performance, that can with propriety be allowed in eccleſiaſtical muſic, has been received in the church ſervice at Peterſburgh, in the Imperial chapel and cathedral of which capital, near a hundred voices are daily employed ; and at Moſcow, in ſeveral churches, when the ſovereign is there, forty or fifty.

The muſic of the Hymnologia of the Ruſſian ambaſſador's chapel in London, is ſung to figurative muſic in three and four parts, diſtinct from the intonations or canto fermo. It conſiſts of ſhort, elegant, and ſimple ſtrains or movements, in the Italian ſtyle, in plain counterpoint, compoſed to Slavonian words, by Bortnianſki, who was ſent to Italy, early in life, by the empreſs Catherine, to ſtudy compoſition.

The taſte for good muſic paſſed from the theatre to the church. The plain chant of the modern Greeks is different from that of other Chriſtian churches. It is more varied than the Gregorian chant ; and that of the hymns rather reſembles the figurative muſic of motets, than canto fermo. The empreſs Elizabeth, who was well acquainted with the kind of counterpoint *à capella*, and had great pleaſure in uniting her voice with the choir, would never allow the Italian *florid ſong* to have admiſſion in the ſacred ſervice ; but ſays the Gotha Almanac, in an abridged hiſtory of the muſic of Ruſſia, 1772, " Italian muſic has invaded even the Greek church as well as the Roman." This voice of complaint borders on *croaking*. We have taken conſiderable pains to obtain information on the ſubject, and have heard the ſervice of the Greek church performed in ſeveral parts of Europe ; and we have been favoured with a ſcore of ſome of the muſic in preſent uſe in that ſervice, compoſed by Bortnianſki, a native of Peterſburgh, and find that it is neither ſo bald and dry as canto fermo, nor ſo florid and flighty as that of the Italian theatre. It is plain counterpoint, *non fugato*, in which the words ſeem well accented, the parts moving all together ; ſo that there is meaſure, clearneſs, tranquil and ſoothing air, pure harmony, and natural and ſimple modulation. Nothing vulgar occurs, nor any thing to remind us of the opera houſe, yet the ſtrains are not without grace or gravity. It ſeems to excite attention by its ſweetneſs and ſimplicity, more than by the art of fugue, or extraneous modulation.

GREEK *Muſic*, *Ancient*. We ſhall here introduce ſome obſervations on the ſubject, extracted from a diſſertation written ſeveral years ago.

Section I.—*Of the Notation or Tablature of Ancient Muſic, including its Scales, Intervals, Syſtems, and Diagrams.*

The muſic of the ancients, according to Euclid, Alypius, and Martianus Capella, was divided into ſeven conſtituent parts : theſe were *ſounds*, *intervals*, *ſyſtems*, *genera*, *modes*, *mutations*, and *melopœia*, or the compoſition of melody. To theſe diviſions, which comprehended only what was denominated harmonics, or the ſcience of muſic, ſtrictly ſo called, were added five other requiſites, no leſs eſſential for a muſician to know, than the preceding ſeven : and theſe were, *rhythm*, or the regulation of cadences in all kinds of movement ; *metre*, or the meaſure of verſes ; *organic*, or the inſtrumental art ; *hypocritic*, or geſture ; and *poetic*, or the compoſition of verſes. And ſtill to theſe diviſions, Ariſtides Quintilianus, and ſome other muſical writers, add *odicum*, or the art of ſinging ; which, indeed, ſeems of more importance to muſic, than either the *organic* or *hypocritic art*. In order to communicate to our readers all the information we are able, upon ſo dark and difficult a ſubject, we ſhall conſider the muſic of the ancient Greeks under ſuch heads only as abſolutely concern muſic, according to our acceptation of the word ; for it is plain that ſeveral of its ancient diviſions more immediately belonged to poetry. Indeed theſe two arts were at firſt ſo intimately connected, and ſo dependent on each other, that rules for poetry were, in general, rules for muſic ; and the properties and effects of both were ſo much confounded together, that it is extremely difficult to diſentangle them.

Leaving, therefore, for the preſent, all other diſtinctions, diviſions, and ſub-diviſions, with which ancient muſical treatiſes abound, we ſhall proceed to fulfil the title of this ſection.

In the ſtudy of modern muſic, the firſt objects of enquiry are the names by which the ſeveral ſounds in the ſcale are expreſſed ; and, if we regard muſic as a language, the ſcale or gammut may be called its alphabet.

Plutarch ſays, that it is not ſufficient for a muſician to know what kind of muſic ſhould be ſet to any particular poem ; he ſhould likewiſe know how to write it down in all the genera, that is to ſay, in the *diatonic* or natural ſcale, conſiſting of tones and ſemitones as at preſent ; in the *chromatic*, in which the ſcale was divided into ſemitones and minor thirds ; and in the *enharmonic* genus moving by quarter tones, and major thirds, as will be explained hereafter.

It does not appear from hiſtory, that the Egyptians, Phœnicians, Hebrews, or any ancient people, who cultivated the arts, except the Greeks and Romans, had *muſical characters ;* and theſe had no other ſymbols of ſound than the letters of their alphabet, which likewiſe ſerved them for arithmetical numbers and chronological dates.

As the notation of the Greeks was imagined in the infancy of the art of muſic, when the flute had but few holes, and the lyre but few ſtrings, the ſimplicity of expreſſing the octave of any ſound by the ſame ſign, as in modern muſic, was not thought of ; the moſt ancient and conſtant boundary of muſical tones having been the *diateſſeron*, or fourth, the extremes of which interval were fixed, though the intermediate ſounds were mutable : and in the manner of tuning theſe conſiſted the difference of intervals in the ſeveral genera.

The Greek ſcale, in the time of Ariſtoxenus, the oldeſt writer upon muſic, whoſe works are come down to us, extended to two octaves, and was called *ſyſtema perfectum, maximum immutatum ;* the great, the perfect, the immutable ſyſtem ; becauſe its extremities formed a perfect conſonance, including all the ſimple, double, direct, and inverted concords, with all the particular ſyſtems ; and it was the opinion of the ancients that this diſdiapaſon, or double octave, was the greateſt interval which could be received in melody.

This whole ſyſtem was compoſed of five *tetrachords*, or different ſeries of four ſounds, and one note added at the bottom of the ſcale to complete the double octave ; whence the ſtring which produced this ſound was called προσλαμβανόμενος, *proſlambanomenos*, or note ſubjoined to the ſcale ; for though this was conſtantly the loweſt ſound in all the modes, it was not included in the tetrachords.

All theſe ſounds had different denominations in the ſyſtem, like our gammut, A *re*, B *mi*, C *fa ut*, &c. beſides two different characters, one vocal, and the other inſtrumental, appropriated to each ſound in the ſeveral modes and genera, for the purpoſe of writing down melodies.

That the fourth was a favourite and important interval in the muſic of the ancients, is plain from the great ſyſtem of two octaves having been compoſed of five of theſe tetrachords, in the ſame manner as the ſcale of Guido is of different hexachords.

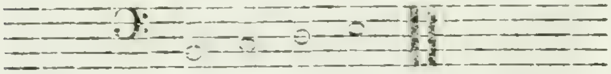
The firſt tetrachord is called by the Greek muſicians *hypaton*, or principal; the ſounds of which are denominated:

1. *Hypate hypaton*, principal of principals;

2. *Parypate hypaion*, next the principal;

3. *Lichanos hypaton*, or index of principals; from its having been played with the index or fore-finger. This third ſound of the firſt tetrachord in the diatonic genus was likewiſe called *hypaton diatonos*.

4. *Hypate meſon*, or principal of the middle or mean tetrachord; for this ſound not only ſerved as the laſt or higheſt note of the firſt tetrachord, but as the firſt or loweſt of the ſecond; whence theſe two tetrachords were called conjoint, or connected. Theſe four denominations of the ſounds in the firſt tetrachord may be compared with the terms B *mi*, C *fa ut*, D *ſol re*, and E *la mi*, in the Guido ſcale; or with the ſounds



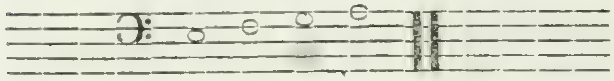
The ſounds of the *meſon*, or middle tetrachord, were placed in the following order:

Hypate meſon, or principal of the mean tetrachord;

Parypate meſon, next to the middle principal;

Lichanos meſon;

Meſe, or middle, as this ſound completes the ſecond tetrachord, and is the centre of the whole ſyſtem. The ſounds of this tetrachord corrreſpond with thoſe which in the baſe of the ſcale of Guido are called E *la mi*, F *fa ut*, G *ſol re ut*, and A *la mi re*, which are equivalent to



The meſe in ancient muſic was of equal importance with the key note in modern muſic: being an octave above the proſlambanomenos, which was the loweſt ſound of the ancient modes, and a kind of key note to them all.

Euclid calls meſe the ſound by which all other ſounds are regulated. And Ariſtotle, in his XXXVIth Problem, ſect. 19. ſays that all the tones of a ſcale are accommodated, or tuned, to the meſe. The ſame author likewiſe tells us, Problem XX. that all melody, whether it moves above or below the meſe, has a natural tendency to that ſound.

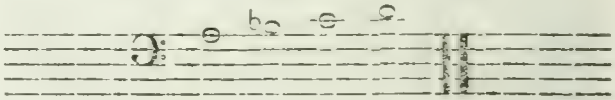
The third tetrachord, beginning by the laſt note of the ſecond, was thence called *ſynemmenon*, the *united*, or *conjunct* tetrachord; the ſounds of which proceed in the following order:

Meſe;

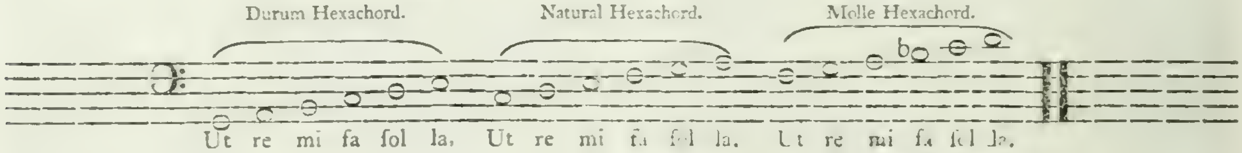
Trite ſynemmenon, or third ſtring of this tetrachord from the top;

Paranete ſynemmenon, penultima of this tetrachord;

Nete ſynemmenon, laſt of the ſynemmenon tetrachord; the four ſounds of which correſpond with thoſe in the centre of our gammut, that are called A *la mi re*, B *fa*, C *ſol fa ut*, and D *la ſol re*, or



After aſcending regularly thus far, up to D, by three conjoint tetrachords, the fourth tetrachord in the great ſyſtem is begun by *deſcending* a minor third to B natural, the octave above the firſt ſound of the loweſt tetrachord. Something of this *dodging* kind is to be found in the ſcale of Guido, divided into hexachords: for, after aſcending ſix notes regularly in the *durum hexachord*, it is neceſſary to deſcend a major third, if we would begin the *natural hexachord*; and when the natural hexachord is completed, if we would begin at the *molle*, it can only be done by a leap of a third below. This will beſt appear by an example in notes:



It appears from the Greek tetrachords, as well as from this example, that neither the ancients nor the early moderns admitted the *ſharp ſeventh* of a key into their ſcales.

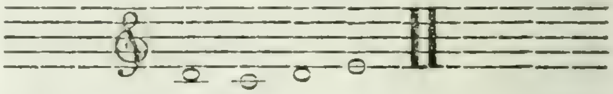
The fourth tetrachord, aſcending, is called *diezeugmenon*, disjunct, or ſeparated, as it begins at B natural, which is not a note in common with any one in the other tetrachords. But though this ſyſtem of four ſounds is only an octave higher than that of the firſt tetrachord, and though the next is but a replicate of the ſecond, we ſhall preſent them to the reader, as the ſeveral ſounds of which they are compoſed have in the Greek muſic different denominations.

The firſt ſound of the ſecond octave, or ſeries of eight ſounds in the ancient great ſyſtem, is *meſe*, and the firſt of the fourth tetrachord begins with the note

Parameſe, near the *meſe*, or middle ſound; the next is called

Trite diezeugmenon, or third ſtring of this tetrachord from the top: then follows the *paranete diezeugmenon*; and laſtly, the

Nete diezeugmenon, or final ſound of this tetrachord; which includes the ſounds B *mi*, C *ſol fa ut*, D *la ſol re*, and E *la mi*, in the middle of the Guido ſcale, or



The laſt ſound of the fourth tetrachord is the firſt of the fifth, which is called the *hyperbolæon*, or ſupreme tetrachord; the ſounds of which aſcend in the following order:

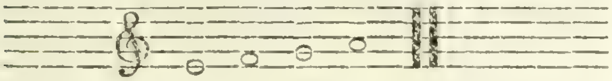
Nete diezeugmenon, laſt of the diezeugmenon tetrachord;

Trite hyperbolæon, third ſtring of the hyperbolæon tetrachord;

Paranete hyperbolæon, penultima of the ſupreme tetrachord;

Nete hyberbolæon, laſt of the ſupreme, or higheſt tetrachord, and of the great ſyſtem, or diagram.

This laſt tetrachord, being added to the ſcale long after its firſt formation, was called *hyperbolæon*, from its ſounds being more acute than the reſt, and beyond the common bounds of the ſcale; in the ſame manner, as, with us, the notes above D in the treble are ſaid to be *in alt.* This tetrachord includes the ſounds E *la mi,* F *fa ut,* G *ſol re ut,* and A *la mi re,* or

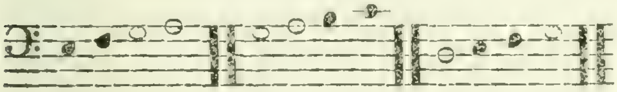


The ancients uſed likewiſe four different monoſyllables ending with different vowels, by way of *ſolmiſation,* for the exerciſe of the voice in ſinging; like our *mi, fa, ſol, la.* Theſe were, for the firſt note of each tetrachord, τᾶ, for the ſecond τῆ, for the third τῶ, and for the fourth, if it did not ſerve as the firſt of the adjoining and relative tetrachord, τε; but if it began a new tetrachord, it was called by the firſt name, τᾶ.

The repetition of theſe monoſyllables is a further proof that the fourth in the ancient muſic ſerved as a boundary to a ſyſtem of four ſounds, in the ſame manner as a hexachord did in the Guido ſcale, and as an octave does for eight ſounds in the more modern practice.

Any interval between the terms of which one or more ſounds intervened, was by the ancients called a *ſyſtem:* EG, for example, conſtituted a ſyſtem of a third minor; EA, of a fourth; EB, of a fifth, &c,

Theſe ſmaller ſyſtems were of different ſpecies; thus there were three kinds of tetrachords, that differed in melody by the poſition of the ſemitone, which was ſometimes at the beginning, ſometimes at the end, and ſometimes in the middle; as in the following example, where the black notes are ſemitones, and the white, tones.



As the Greeks uſed all the four and twenty letters of their alphabet for muſical characters, or ſymbols of ſound; and as their moſt extenſive ſyſtem or ſcale did not exceed two octaves, or fifteen ſounds, it ſhould ſeem as if their ſimple alphabet was more than ſufficient to expreſs them; for their muſic being at firſt only a notation of their poetry, the rhythm, or air, muſt have been determined by the metre of the verſes, without the aſſiſtance of ſigns of proportion peculiar to muſic. But ſuppoſing it was neceſſary for them to have different characters to expreſs the different feet of the verſe, it is certain that vocal muſic was in no want of them; and inſtrumental being chiefly vocal muſic played by inſtruments, had likewiſe no need of them, when the words were written, or the player knew them by heart.

However, in order to multiply theſe characters, the letters of their alphabet were ſometimes written in capitals, and ſometimes ſmall; ſome were entire, ſome mutilated, ſome doubled, and ſome lengthened; and beſides theſe diſtinctions in the form of the letters, they had others of ſituation, ſometimes turning them to the right, ſometimes to the left; ſometimes inverting, and ſometimes placing them horizontally; for inſtance, the letter *gamma,* by theſe expedients, ſerved to expreſs ſeven different ſounds:  Some of the letters were alſo barred, or accented, in order to change their ſymbolical import; and theſe ſtill not ſufficing, they made the common grave and acute accents ſerve as ſpecific muſical notes.

It is a matter that has been long diſputed among the learned, whether *accents* were originally *muſical characters,* or marks of *proſody.* It is in vain to ſet about determining a queſtion concerning which the proofs on both ſides are ſo numerous. (See Gally and Spelman *againſt accents,* and Primatt and Forſter in defence of them.) Mr. Weſt is firmly of opinion "that accents were originally *muſical notes,* ſet over words to direct the ſeveral *tones* and inflexions of the voice, requiſite to give the whole ſentence its proper harmony and cadence." (Pind. vol. ii.) And the abbé du Bos, who frequently by a peremptory deciſion cuts the knot of ſuch difficulties as he is unable to untie, aſſerts, without ſufficient proof, that as poets originally ſet their own verſes, they placed for this purpoſe a figure, or accent, over each ſyllable. So that, according to this writer, we are at preſent not only in poſſeſſion of the *poetry* of Homer, Pindar, Anacreon, and Sappho, but their *muſic.* Why then do we complain of the total loſs of Greek muſic? (See Reflex. Critique, c. iii. p. 85.) But as muſic had characters different from accents ſo early as the time of Terpander, to whom the invention is given by the Oxford Marbles, which place this event about ſix hundred and ſeventy years before Chriſt; and as accents for proſody are likewiſe proved to be of high antiquity, it ſeems as if there could have been no neceſſity for the ancients to uſe one for the other.

But it has already been remarked that the letters of the alphabet, though turned, diſtorted, and mutilated, ſo many different ways, were inſufficient to expreſs the ſounds of all the modes in the three genera; ſo that recourſe was had to accents, as the ſcale became more extended, in order to augment the number of characters. And Alypius, in the enumeration of the notes in the enharmonic genus, tells us, that *trite ſynemmenon* is repreſented by *beta* and the *acute accent;* and *paranete ſynemmenon enarmonios* by *alpha,* and the *grave accent.*

This is a proof that the accents were known at the time of Alypius, and were then uſed chiefly for proſody, not muſic, for which they were only called in occaſionally. Indeed they are mentioned as accentual marks by writers of much higher antiquity than Alypius; for not only Cicero and Plutarch, but Ariſtotle and Plato, ſpeak of them as merely regarding the elevation and depreſſion of the voice in ſpeech. However, in the early Greek and Roman miſſals, as will be ſhewn hereafter, the muſical characters uſed in *canto fermo,* ſeem to have been only *lengthened accents.*

Theſe various modifications of letters and accents in the Greek notation compoſed in all one hundred and twenty different characters, which were ſtill conſiderably multiplied in practice; for each of theſe characters ſerving many purpoſes in the vocal as well as inſtrumental tablature or gammut, and being changed and varied according to the different modes and genera, as the names of our notes are changed by different cleffs and keys, the one hundred and twenty Greek characters produced one thouſand ſix hundred and twenty notes!

Two rows of theſe characters were uſually placed over the words of a lyric poem; the upper row ſerving for the voice, and the lower for inſtruments.

If we had not the teſtimony of all the Greek writers who have mentioned theſe characters, for their uſe and deſtination, it would be natural to ſuppoſe that the double row of different letters placed over each other, and above the words of a poem, were intended to expreſs *different parts,* with reſpect to *harmony;* as with us, in modern muſic, the treble notes are written over the baſe, and the firſt treble over the ſecond; but Alypius, who is extremely minute in his inſtructions concerning the uſe of theſe characters, in all theſe modes, tells us, in expreſs terms, that the upper line of the notes is for the words, and the lower for the lyre. (Σημεια τα μεν ανω, της λεξεως· τα δε κατω της κρουσεως. Introd. Muſ. edit. Meibom. p. 2.) We are told, not only by Alypius, but by Gaudentius, p. 23, that of the two rows of letters uſed for muſical characters, the upper is for the words, that is, *to be ſung*, and the under *to be played.* And he afterwards proves them to have been uniſons to each other, both by his definitions and by placing them oppoſite to the ſame ſound in all the ſcales.

In this author, the notes of the great ſyſtem of the Lydian mode in the diatonic genus are arranged in the following order:

7 ⊤ R Φ C P M I Θ Γ Ʊ Z E Ʊ ⊖ ⅄ M′ I
⊢ Γ L F C ◡ Π < V N Z ⊏ ⊔ Z η ⊬ Π′ <′

And theſe he defines in ſuch a manner as leaves no room to doubt of the identity of their ſignification.

It is ſomewhat ſtrange that the notes for the voice in ancient muſic ſhould be placed *above* thoſe for the lyre, and conſequently further from the words. Meibomius, in his preface, has, however, given a curious reaſon for this cuſtom, from a fragment of Bacchius, ſenior: "The upper line of notes is for the poem, the lower for the lyre; becauſe the mouth, which alone gives utterance to the words, is placed by nature above the hands, which produce tones from the inſtrument.

7⊢ *Proſlambanomenos*, an imperfect *Zeta*, and *Tau* placed horizontally.

⅂ Γ *Hypate hypaton*, an averted *Gamma*, and a *Gamma* direct.

R L *Parypate hypaton*, an imperfect *Beta*, and a *Gamma* inverted.

Φ F *Hypaton diatonos*, a *Phi*, and a *Digamma*.

C C *Hypate meſon*, *Sigma* and *Sigma*.

P ◡ *Parypate meſon*, *Rho*, and *Sigma* inverted

M Π *Meſon diatonos*, *Mu*, and a lengthened *Pi*.

I < *Meſe*, *Iota*, and a horizontal *Lambda*.

Θ V *Trite ſynemmenon*, *Theta*, and an inverted *Lambda*.

Γ N *Synemmenon diatonos*, *Gamma* and *Nu*.

Ʊ Z *Nete ſynemmenon*, an inverted *Omega* and a *Zeta*.

Z ⊏ *Parameſe*, *Zeta*, and *Pi* placed horizontally.

E ⊔ *Trite diezeugmenon*, *Epſilon*, and an inverted *Pi*.

Ʊ Z *Diezeugmenon diatonos*, as Nete ſynemmenon, which was the ſame ſtring in the lyre.

⊖ η *Nete diezeugmenon*, horizontal *Phi*, and a ſmall *Eta* lengthened.

⅄ ⊬ *Trite hyperbolæon*, an inverted *Upſilon*, and an imperfect *Alpha*.

M′ Π′ *Hyperbolæon diatonos*, *Mu*, and a lengthened *Pi*, accented.

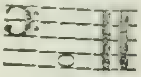
I <′ *Nete hyperbolæon*, *Iota*, and an accented *Lambda*, placed horizontally.

It is from the indefatigable labour of the learned Meibomius, in his Commentaries upon the ancient Greek muſicians, particularly Alypius, that we are able to decypher theſe characters; which, before his time, had been ſo altered, corrupted, disfigured, and confounded, by the ignorance or negligence of the tranſcribers of ancient manuſcripts, that they were rendered wholly unintelligible.

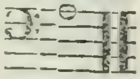
With our utmoſt ſtudy, reading, and contemplation, we could reduce the Greek notation to no order, nor aſcertain whether it was to be read upwards or downwards. The neglect of theſe diſtinctions will introduce an univerſal ſcepticiſm concerning every part of ancient muſic.

Galilei, Zarlino, Bontempi, Tevo, M. Rouſſeau, Dr. Brown, and others have aſſerted, that the terms *high* and *low* had different acceptations among the ancients, from thoſe in which they are underſtood by the moderns, without guarding, as they ought to have done, againſt ſuch conſequences, with reſpect to the ſituation of the ſcale, as it was natural for the reader to draw from that aſſertion.

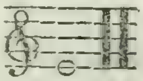
At length, an infallible rule preſented itſelf to us in the works of the great Euclid, who has been regarded for ſo many ages as the legiſlator of mathematicians, and whoſe writings have been their code. In his ſection of the Canon, p. 37, edit Meibom. he repreſents *proſlambanomenos* by the *whole ſtring:* ſo that, if any thing concerning ancient muſic can be made certain, it is, that this whole ſtring repreſented the *loweſt ſound* in the Greek ſcale, which, in the Hyperborian mode, was equivalent to the note A



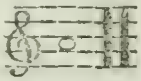
Half the ſtring, *Meſe*, its octave, a,



Third part, *Nete diezeugmenon*, fifth of the octave, e, - - - -



And the fourth part of the ſtring, *Nete hyperbolæon*, the double octave, aa, -



which include all the concords that the ancients admitted. Eight ninths of the ſtring are allotted to the ſound *Hypate bareia gravis*, which is B in the baſe, one tone higher than *proſlambanomenos*, or A.

This repreſentation of the whole ſtring and its diviſions into harmonic and aliquot parts, muſt put an end to every doubt concerning the order of the ſcale, which may have ariſen from the inverted application of the words *high* and *low*, conſtantly occurring in all the more ancient and authentic Greek writers on muſic.

Sect. VIII.—*Whether the Ancients had counterpoint or muſic in parts.*

This is a ſubject which has given birth to many learned diſquiſitions and diſputes; and as it long remained a mere matter of opinion, thoſe who believed, and thoſe who denied the point in queſtion, conſequently treated each other with all due polemic acrimony. The champions for antiquity thought themſelves involved in the controverſy; and whether they were poſſeſſed of muſical knowledge, or were ſenſible to the charms of harmony, or not, they determined to regard every man as an enemy to ſound literature, who did not ſubſcribe to the articles of their faith.

A poem, called "Le Siècle de Louis le Grand," written by Charles Perrault, of the Academy of Sciences, and brother to Claude Perrault, the famous phyſician and architect, occaſioned the long and acrimonious diſpute between him and Boileau, and ſoon brought on a general war among the learned throughout Europe, concerning the ſuperiority of the ancients or moderns, with reſpect to arts, ſciences, and literature. This piece was firſt read by the author at the Academy of Sciences in 1687, and was ſoon followed by his "Parallele des Anciens et des Modernes." The notes to Boileau's tranſlation of Longinus were intended as a reply to Perrault, and are full of bitter invectives, not only againſt him, but the moderns in general. Racine, La Bruyere, and Fontenelle, took ſides in the quarrel, which in France was kept alive, with great animoſity, for near thirty years.

In England, the controverſy between ſir William Temple and Mr. Wooton, Mr. Boyle and Dr. Bentley, and Swift's "Battle of the Books," were conſequences of this quarrel.

Thoſe who had written *ex profeſſo* on muſic, had frequently differed in their opinions concerning counterpoint having been known by the ancients, previous to the learned, in general, intereſting themſelves in the diſpute; and before we give our own opinion, as an individual, it is incumbent on us, as an hiſtorian, to inform our readers, who were the principal champions on both ſides. Would it not render our article too long, the reaſons aſſigned by each for ſeizing his ſword, that is, his pen, in the quarrel, ſhould likewiſe have a place here. But our limits will only allow us to ſay, that the moſt eminent defenders of ancient harmony in our ſenſe of the word, are Gaffurio Zarlino, Gio. Battiſta Doni, Iſaac Voſſius, Zaccharia Tevo, the abbé Fraguier, and Mr. Stillingfleet, author of "Principles and Power of Harmony."

Their oponents are Glarianus, Salinas, the cavalier Hercules Bottrigari of Bologna, Artuſi, Cerone, Kepler, Merſennus, Marſilius Ficinus, Kircher, Claude Perrault, and the late elegant and learned poet Mr. Maſon, who had ſtudied modern muſic, and has left his decided opinion againſt the ancient Greeks having cultivated counterpoint. (Hiſt. Muſ. vol. i. p. 125.) To theſe we may add Bontempi, the firſt Italian muſical hiſtorian, the learned Dr. Wallis, M. Burette, who has explored the ſubject, and conſidered it in all its ramifications. Padri Martini of Bologna, a learned and diligent inquirer, has given a ſpecimen (Stor della Muſ. t. i. p. 174.) of ſuch meagre counterpoint as was likely to have been produced without the uſe of imperfect concords, which the Greeks termed diſcords. The late ſhrewd and penetrating critic J. J. Rouſſeau is very explicit upon this ſubject in his "Muſical Dictionary," at the article *Counterpoint*, which he terminates by ſaying, "It has long been diſputed whether the ancients knew counterpoint; but it clearly appears from the remains of their muſic and writings, eſpecially the rules of practice, in the third book of Ariſtoxenus, that *they never had the leaſt idea of it*."

After this liſt of the moſt reſpectable writers on both ſides of this long diſputed queſtion, it now remains to tell the reader ingenuouſly our own ſentiments: and to confeſs the truth, we will venture to ſay, that we do *not* believe the ancients ever did uſe *ſimultaneous harmony*, that is, *muſic in different parts*; for without thirds and ſixths it muſt have been inſipid; and with them, the combination of many ſounds and melodies moving by different intervals, and in different times, would have occaſioned a confuſion, which the reſpect that the Greeks had for their language and poetry would not ſuffer them to tolerate.

Sect. IX.—*Of the Dramatic Muſic of the Ancients.* See DRAMATIC *Muſic*.

The Greek dramas conſiſted of ſoliloquy, dialogue, and chorus, and it has naturally been ſuppoſed, that theſe were ſung to different kinds of muſic. Soliloquies full of ſentiment and paſſion had probably a different, more elaborate, and refined melody, than the dialogues; but the chorus muſt neceſſarily be ſet to meaſured muſic, or the performers, if left *ad libitum*, could never have kept together.

Sect. X.—*Of the effects attributed to the muſic of the ancients.*

Materials for this part of our diſſertation are ſo numerous, that if we were only to preſent the reader with all the ſtories that have been related by the moſt grave and reſpectable hiſtorians and philoſophers of Greece and Rome, concerning the moral, medicinal, and ſupernatural powers of ancient muſic, this ſection would be as full of the miracles of muſicians, as the "Golden Legend" is of thoſe operated by the ſaints. The credulous and excluſive admirers of antiquity have, however, ſo long read and reverenced all theſe narrations, that they are impreſſed by them with an extravagant idea of the excellence of ancient muſic, which they are very unwilling to relinquiſh; and yet, after a moſt careful inveſtigation of the ſubject, and a minute analyſis of this muſic, by examining its conſtituent parts, we have not been able to diſcover that it was ſuperior to the modern in any other reſpects than its ſimplicity, and ſtrict adherence to metrical feet, when applied to poetry. For, as *muſic*, conſidered abſtractedly, it appears to have been much inferior to the modern, in the two great and eſſential parts of the art, *melody* and *harmony*.

We have conſidered the marvellous effects aſcribed to ancient muſic, under three ſeveral heads:

Firſt, in ſoftening the manners, promoting civilization, and humanizing men, naturally ſavage and barbarous:

Secondly, its effects in exciting, or repreſſing the paſſions:

And thirdly, its medicinal power, in curing diſeaſes.

And we think, that the whole may be conſtrued into poetical fables, allegories, and vulgar errors. Many ſtrange ſtories of the power of muſic over man and beaſt have gained admiſſion into books, even in this philoſophical and unbelieving age, at which poſterity will doubtleſs ſtare!

GREEK *Grammar*. See GRAMMAR.

GREEK *Language*, the language of the Greeks. Whether we conſider the high antiquity of this tongue, its varied excellencies, the unrivalled models of compoſition which it contains, or the extenſive influence which the ſtudy of it has produced on the more modern dialects of Europe, it claims, in an eminent degree, the attention of learned men, as a ſubject no leſs curious than uſeful. The advantages to be derived from the ſtudy of thoſe authors who have written in this tongue, are too notorious to need deſcription, and are recommended to us by the united teſtimony of the learned in every age and country. The Greeks have left the moſt durable monuments of human wiſdom, fortitude, magnificence, and ingenuity, in their improvement of every art and ſcience, and in the fineſt writings upon every ſubject neceſſary, profitable, elegant, or entertaining. They have furniſhed the brighteſt examples of every virtue and accompliſhment, natural or acquired, political, moral, or military; they excelled in mathematics and philoſophy; in all the forms of governments, in architecture, navigation, commerce, war; as orators, poets, and hiſtorians, they ſtand as yet unrivalled, and are likely to continue unrivalled for ever; nor are they leſs to be admired for the exerciſes and amuſements they invented and brought to perfection, in the inſtitution of their public games. Nor can we become ſenſible of theſe admired excellencies in any of the beſt tranſlations from the Greek. They may indeed communicate ſome knowledge of what the originals contain: they may preſent us with propoſitions, characters, and events; but allowing them to be more faithful, more accurate than they really are, or can well be, ſtill they are no better than copies in which the ſpirit and luſtre of the originals are in a great degree neceſſarily loſt. The powers of the Greek are vaſtly beyond thoſe of any other tongue. Whatever the Greek writers deſcribe is always felt, and almoſt ſeen; motion and muſic are in every tone, and enthuſiaſm and enchantment poſſeſs the mind when we peruſe them with taſte and judgment.

The Greek tongue, as it was ſpoken in different provinces, was divided into different *dialects*, called the *Attic*, the *Ionic*, the *Doric*, and the *Æolic*. The Attic is that which was uſed at Athens, and in the adjacent country; thoſe who have particularly diſtinguiſhed themſelves in this dialect, are Thucydides, Ariſtophanes, Plato, Iſocrates, Xenophon, and Demoſthenes. The Ionic differed very little from the ancient Attic; but having afterwards made its way into ſome towns of Aſia Minor, and into the adjacent iſlands which were colonies of the Athenians and Achaians, (among which are reckoned Samos, Miletus, Epheſus, Smyrna, and ſome others,) it imbibed a new tincture, and fell very far ſhort of that delicacy to which the Athenians afterwards attained. The principal writers in this dialect were Hippocrates and Herodotus. The Doric firſt prevailed among the Lacedæmonians and the inhabitants of Argos. It travelled afterwards into Epirus, Sicily, Rhodes, and Crete. This dialect has been uſed by Archimedes and Theocritus, (both of Syracuſe,) and Pindar. The Æolic was ſpoken at firſt among the Bæotians and their neighbours, and afterwards it paſſed into Æolia, a province of Aſia Minor, between Ionia and Myſia, which included ten cities, all Greek colonies. The chief writers in this dialect were Sappho and Alcæus, of whoſe writings little has ſurvived the loſs of ancient learning; but this idiom is occaſionally blended with the uſe of the other dialects in the compoſitions of Homer, Theocritus, Pindar, and others. It may be remarked farther that the lapſe of time which occaſioned the difference of theſe dialects, as they aroſe from a common ſtem, has moreover cauſed them to differ from themſelves. For inſtance, in the Attic there is a wide diſtinction between the ſtyle of Demoſthenes, and that of Thucydides. Nor has the Ionic dialect invariably continued the ſame, the people of Aſia ſpeaking it differently from the old Ionians of Greece, who followed the ancient language of Athens, and the ſame obſervation holds in regard to the Dorians and Æolians.

The ramification of the Greek tongue into its ſeveral dialects, while it forms one leading cauſe of its copiouſneſs, occaſions one of the moſt ſerious difficulties in the acquiſition of it by learners. This difficulty, however, will be much diminiſhed, if the dialects be reduced to thoſe unavoidable changes, which are founded in the nature of language, and in the organs of ſpeech. The changes we mean are ſuch as flow from the fluctuation of the vowel ſounds, from the different manner of combining, or of reſolving any two concurrent vowels, and laſtly, from the ſubſtitution or interchange of the homogeneous conſonants, *i. e.* the conſonants of the ſame organs.

Oriental grammarians, with much propriety, have divided the conſonants into three claſſes, correſponding with the organs employed in ſounding them. Thus π, β, φ, being ſounded by the lips, are hence called *labials*. On the other hand, τ, δ, θ, ς, λ, ν, ρ, enunciated by a contact of the tongue with the extremities of the upper teeth, are, for a ſimilar reaſon, ſtyled *dentals*; while κ, γ, χ, uttered by a contraction of the *larynx*, receive the name of *gutturals*. This diſtribution of the conſonants, though here confined to the Greek alphabet, neceſſarily extends to any other ſyſtem of letters, and well deſerves the attention of him who would acquire a philoſophical acquaintance with the origin and derivation of words. To the interchange of the homogeneous conſonants, it is chiefly owing that the primæval language of men, at firſt rude and barren, became copious and refined (the ſame original term hence ſplitting into many), was afterwards diverſified into diſtinct dialects, and at length loſt in diſtinct languages. Nor is it, we conceive, beyond the reach of philological enquiries to prove that the ſimple terms of any one language have their kindred terms in all other languages, diſguiſed indeed by the differences of character, termination, and meaning; and that they may be traced back through the ſeveral ſtages of ſocial life, till they meet, like ſo many ſhoots, in one common root.

The Greek language is a very copious ſubject, and a full account of it would carry us beyond the limits neceſſarily preſcribed by our plan; we ſhall therefore content ourſelves with ſome remarks calculated to aſcertain its origin, and to unfold thoſe analogies by which it grew from a few ſimple roots to the copiouſneſs and refinement which diſtinguiſh it beyond moſt other tongues.

In enquiring into the origin of the Greek tongue, or in referring it to a higher dialect, we of courſe mean its roots or primæval words, which were ſimple, few in number, and conſiſting of two, three, or at moſt four letters; while its compound terms, which are exceedingly numerous and diverſified, muſt have been indigenous, the products of time, and of improvement in knowledge and the arts of life, long after the introduction of its more elementary parts into Greece. With this limitation we have no heſitation in ſaying, that the ſimple words of the Greek language are all derived from the Hebrew, Arabic, and Perſian, and principally from the firſt of theſe tongues. And for the affirmation that the Greek is derived from the Hebrew, or that the Greek primitives are Hebrew radicals, we offer the following obſervations. Moſes, in the tenth chapter of Geneſis, the fountain head of univerſal hiſtory and geography, enumerates thoſe heads of ſeparate families by whom the earth was divided after the flood. He deſcribes them by thoſe names which the nations that ſprung from them, or the countries they ſeverally occupied, retained in his time. By thoſe parts of the earth, which he calls איי הגוים, or *the iſles of the nations*, it is underſtood that he means *Europe*, and its adjacent iſlands. Theſe were divided by the ſons and grandſons of *Japheth*, or rather by *Gomer* and *Javan*, and their ſons,—"In their lands every one after his tongue, after their families in their nations." This diviſion muſt have been regularly conducted. It muſt have taken place in the time of the patriarchs here mentioned; for the act was *theirs*, and the nations retained their names to the time of Moſes; nay many of them long afterwards, for we find them recognized by hiſtory and geography. *Javan* is well known as the parent of the *Greeks*, the name *Ionians* being anciently applied from him to the ſeveral branches of that nation. Τους Θρακας, και Αχαιους, και Βοιωτους Ιωνας εκαλουν. *Heſychius.* Παντας Ελληνας Ιωνας οἱ Βαρβαροι εκαλουν. But it appears from the ſacred hiſtory that Javan ſpoke the Hebrew tongue; and he, with the colony under him, muſt have introduced it with them, and made it the firſt language of Greece. The letters of the Greek tongue refer its origin to the ſame oriental ſource; for they are nearly the ſame with the *Samaritan* when inverted, or written after the European manner, from left to right; and with little variation they have ever retained the names of the Samaritan or Hebrew alphabet. This is confirmed by Diodorus the Sicilian, lib. v. who gives it as the opinion of perſons in his days, that letters were invented by the *Syrians*, from whom the Phœnicians firſt learnt their uſe, and then communicated them to the Greeks. Theſe Aſſyrians, Herodotus deſcribes (l. iii.) as the inhabitants of Jeruſalem, to which he gives the name of *Cadytius*, the name it had of old, and ſtill continues to have in the Eaſt. The authority of Herodotus and Diodorus, Pliny, it is probable, chiefly had in view, when he ſays, Hiſt. l. viii. c. 58; "Literas ſemper arbitror Aſſyrias fuiſſe; ſed alii apud Ægyptios a Mercurio, ut Gellius; alii apud Syros repertas volunt, utique in Græciam intuliſſe e Phœnice Cadmum ſedecim numero."

From the ſame authority it appears that the Phœnicians only changed the ſhape or form of the Hebrew letters, and were not the firſt who diſcovered them; nor were they the firſt who introduced the uſe of letters into Greece. For Diodorus declares that Linus compoſed a book concerning the exploits of the firſt Dionyſius in *Pelaſgic characters*, and that the ſame were uſed by Orpheus and Pronapides, the preceptor of Homer, lib. iii. Zenobius writes that Cadmus ſlew Linus for teaching characters differing from his: and Pauſanias in his Attics aſſures us, that he himſelf ſaw an inſcription upon the tomb of Corœbus, who lived at the time when Crotopus, a contemporary with Deucalion, was king of the Argives. The firſt tribe who ſettled in Greece were called *Pelaſgi*, (probably from πελαγος, *ſea*,) which name correſponds to our appellation of *iſlanders;* and is the ſame in import with what Moſes calls the firſt inhabitants of Europe, *the iſles of the nations.* The firſt European coloniſts, it appears to us probable, with the uſe of the primæval language of men, introduced its *letters* or *characters*, which, by their diſperſion and conſequent relapſe into barbariſm, neceſſarily became corrupted, though not entirely loſt; while Cadmus introduced the original alphabet in a more pure or improved ſtate. The Phœnician and the Pelaſgic characters, previouſly uſed in Greece, were eſſentially the ſame, and different only in degrees of refinement: and it is a remarkable fact, that after the introduction of the Cadmean alphabet the Pelaſgic has left no trace of its exiſtence, which in our opinion clearly proves that theſe two ſyſtems, in conſequence of their affinity, coaleſced, and have been perpetuated under one and the ſame form. See Lennep. De Analogia, vol. iii. p. 28.

The introduction of the Phœnician alphabet preceded the Chriſtian era only about fifteen centuries; and it is curious to obſerve the form and extent of it as taught by Cadmus. It ſtood thus, α, ε, ι, ο, υ; β, π; γ, κ; δ, τ; σ, ρ, λ, μ, ν. Hence it appears that the diviſion of the Greek or Phœnician alphabet correſponds to that which obtains in all the Oriental languages; the vowels being ſeparated from the conſonants, and the conſonants themſelves claſſed conformably to the organs employed in ſounding them. It appears farther, that the alphabet at this time exiſted in its moſt ſimple ſtate, and was afterwards enlarged by combining its more ſimple elements. Thus ε repeated gave birth to η, which conſiſts of one epſilon turned backwards to face another, as ε϶, and thence abbreviated into the form of η. Alſo ο was doubled, which formed the long ω, its figure having faithfully preſerved the double οο blended into one letter. The early Greeks expreſſed the aſpirate by the figure H, which the Latins have hence copied: and this letter combining with the *labials* β, π, gave birth to φ; with the gutturals γ, κ, to χ; with the *dentals* δ, τ, to ϑ. Moreover, the ſibilant σ coaleſcing with π, β, φ, produced ψ; with κ, γ, χ, produced ξ; with τ, δ, ϑ, produced ζ. The alphabet of Cadmus was accordingly augmented by the following letters η ω, φ ϑ χ, ξ ψ ζ. The Greeks, wiſhing to diſplay their own improvements, have dignified theſe compound letters (which in reality are only combinations of the ſimple elements,) as the *inventions* of Palamedes in the times of the Trojan war, or of Simonides of Cos, who flouriſhed about 800 years before Chriſt. See Bent. on Phalaris, p. 241.

Theſe eight letters, by whomſoever formed, were firſt received by the Ionians, whoſe alphabet, conſiſting of four-and-twenty letters, was called the *Ionic*, in oppoſition to the *Attic alphabet*, which conſiſted of merely the ſixteen ſimple elements, the Athenians having, with the other ſtates of Greece, for a long time rejected the additional letters, though after the death of Euripides, in the archonſhip of Euclid, they were admitted by public authority; and thus the Greek alphabet, as we now find it, became the common alphabet of all the Greeks.

Laſtly, the Greek language is of Hebrew extraction, becauſe its roots will, upon examination, appear to have been no other than radicals of that language. In proof of this aſſertion we give the following ſhort liſt of them as ſpecimens.

אב, *ab* or *aab*, ſtem, root; hence απο, origin, beginning. It means alſo *pubes*, youth; hence ηβη. אבה, *abe*, to love; hence ηπιος, mild. איש, *aes*, man, one, εις, οιος, ſolus. אכל, *akal*, to eat, κολος, a piece of bread, χειλος, the lip, χιλος, food, χιλοω, to feed; κυλην, *culina*, kitchen. אלף, *alph*, αλφω, αλφαω, αλφαιω, αλφαινω, αλφεω, to ſtudy, invent, inveſtigate; אמל, *amal*, to be languid, feeble, αμαλος, tender; אמה, *ame*, ωμος, the ſhoulder; אמן, *amen*, to be true, hence αμην, μην, μεν. This word in Hebrew alſo means to defend with fidelity; hence αμυνω and αμυναθω, to aid, protect; אים, *aeem*, ωμος, cruel; אי, *aee*, an iſland; hence αια, the earth; אפן, *aphen*, a wheel; hence απηνη, a wain or carriage; ארך, *arek*, to ſtretch forward, ορεγω; ארון, *a cheſt*, ερειον, *urna;* ארץ, *aretz*, in Chaldean ארק, earth, to cultivate the earth, hence εργον, εργαζομαι, in Syriac, ארע, *aro;* hence αροω, to plow, αρουρα and ερα, terra; ארר, *arr*, to curſe, hence αρα, αραομαι; אש, *fire*, εσχαρα, a hearth; אשה, a ſacrifice, εστιαω, to feaſt, εσθιω, to eat, Ηφαιστος, Vulcan, is אבאשת, father of fire, or of ſacrifice; בא, *baa*, βαω, to go; בגה, *baga*, φαγω, to eat; בהמה, *beme*, ποιμνη, a flock; במה, *buma*, a high place, where an altar was raiſed, βωμος, an altar; בין, *been*, to underſtand, πινυω and πινυτος, prudent; ברך, *buruk*, to pray, bleſs, to rain, βρεχω, to rain, πρωκη, a drop. Hence alſo in the ſenſe of to ſupplicate came βρεγμα, the bending of the knee, ſupplication. Hence moreover βρακκαι, a covering for the knees, breeches; גאה, *gae*, γαιω, to glory; גור, to move round, tarry, γυροω, *gyro*; מגור, *magur*, a place of abode, μεγαρον, a reſidence; דין, *deen*, to contend, to litigate; τεινω, δειναζω, δεινος; דיק, *deek*, a defence, τειχος, a wall; דמה, *dama*, to ſubdue, δαμαω; הוד, *eud*, to venerate, to celebrate, praiſe, αιδω, αειδω, to ſing, αιδεω, to reverence, αυδαω, to expreſs; היה, εω or ειμι, *to be;* זון, to entertain, ξενος, a hoſt, ξενιζω; זוע, *zuo*, to move, σευω; חוה, *khue*, to illumine, αυω, ευω; חרי, ηρως, a hero, κυριος, a lord; חתת, to be inferior, ηττaω; טלא, *tula*, to ſtain, τιλαω; טלה, *tule*, a lamb, ταλασιον, κτιλος; יין, *een*, οινος, wine; οινων and οινωνη, a wine-cellar; ינה, *ene*, to afflict, ανια, ανιαω; כוה, *kue*, to burn, καιω, καω; כח, *kuk*, power, κικυς, κικυς, κικυω; להג, *leg*, to read, to collect, λεγω, λογος, λογιζω; מהל, to pollute, μολυς, μολυνω; מום, *mom*, a ſtain, μωμος, αμωμος, without a ſtain, blameleſs, μωμαω, to cenſure; נוה, *noe*, to inhabit, ναιω; עור, *aor*, to excite, ορω; פרש, *phereſh*, to explain, φραζω; צהר, *zer*, to ſhine, σειριαω, σειριαινω, to ſhine, σειριος, Sirius, σειρ, the ſun; קול, *kol*, to call, καλεω; קוה, *kue*, to expect, lean upon, κιω; תורבה, *turbe*, τυρβα, turba, a multitude, alſo θορυβος, a tumult, θορυβεω; רוה, *roe*, ρευω, ροω, ραινω, ερωεω, ερευδω, to flow, to water; רפא, *rapha*, to repair, to ſew, to heal; ραπτω, ραφις, a needle, ραφιον, a claſp; שוע, *ſoa*, σαω, to ſave; שיר, *ſeer*, συριγξ, συρισσω, to play on a pipe; תור, *tor*, to inveſtigate, contemplate, θηραω, θεωρεω; תנין, *tanin*, a viper. . . .

Theſe examples are ſufficient to ſhew how the Greek has been derived from Hebrew roots. Some thouſands of Greek primitives owe their origin to the ſame ſource; and it is not too much to ſay that, if the Hebrew language had been preſerved in the full extent in which it once flouriſhed, not a Greek term could be named, which might not be traced to ſome one of its roots. But as its records are comparatively ſo ſcanty, many of the parent terms of Greece may more immediately be found in the kindred tongues of Syria, Chaldea, Arabia, and even Perſia, which laſt, though different in ſtructure from the Greek, contains a multitude of its radical terms. The concluſion that Greek originally flowed from the Hebrew tongue, ſerves to explain many of the properties which diſtinguiſhes this celebrated language, and to correct many errors into which learned men have fallen in treating this ſubject.

"The eaſtern tongues, ſays Dr. Gillies, (Hiſtory of Greece, vol. i. p. 15.) are in general extremely deficient in vowels. It is, or rather was, much diſputed, whether the ancient orientals uſed any characters to expreſs them. Their languages, therefore, muſt have had an inflexible thickneſs of ſound, extremely different from the vocal harmony of the Greek, which abounds not only in vowels, but in diphthongs. This circumſtance denotes, in the Greeks, organs of perception more acute, elegant, and diſcerning. They felt ſuch faint variations of liquid ſounds as eſcaped the dulneſs of Aſiatic ears, and invented marks to expreſs them. They diſtinguiſhed in this manner, not only their articulation, but their quantity, and afterwards their muſical intonation." We do not think this obſervation altogether juſt, but think it rather founded in a miſconception of the oriental languages. In theſe every conſonant included in itſelf the vowel neceſſary to its enunciation; and while they thus preſented a ſeries of conſonants to the eye, each in pronunciation is accompanied with its appropriate vocal ſound, which rendered every word juſt as many ſyllables as it had of conſonants, and gave to the language an exact mixture of vowels and conſonants. When the Hebrew tongue ceaſed to be a living language, its true pronunciation was of courſe loſt; and with it was loſt the ſound and even the exiſtence of the included vowel; and to ſupply this loſs were invented the vowel points in Hebrew, Arabic, and the accents in Greek, which appear to be of kindred or rather of the ſame invention with the diacritical marks in the Aſiatic tongues. The early Greeks, being ſenſible of the included vowel in the parent tongue, gave it a ſeparate exiſtence, by annexing it to the conſonant: and as this vowel, though originally the ſame and always ſhort, was liable to fluctuation, and to perceptible difference of ſound, it naturally gave birth to the ſeveral ſhort vowels. In Homer the digamma, which was a labial conſonant, interpoſed between two vowels, which otherwiſe would have formed a diphthong. And this circumſtance might lead us to conclude that the early Greeks conformed to the Aſiatic tongues in rejecting the uſe of diphthongs, and that the uſe of diphthongs prevailed only as the digamma was laid aſide. In the more ancient languages of Aſia, all the included vowels were ſhort, and every vowel that had an independent form was probably *long:* but ſhort as well as long vowels came in time to have a ſeparate exiſtence; and the Shanſcrit, ſo far from being deficient in vowels, can boaſt of *ſixteen,* a number more than the double of thoſe in Greek.

We remark, in the ſecond place, that the derivation of the Greek primitives from the oriental tongues will, in general, ſet aſide as nugatory and erroneous the derivations of the ancient *ſcholiaſts,* and of thoſe modern lexicographers who have adopted their explanations. Theſe ſcholiaſts and grammarians are valuable as expounders of the Greek text; but as they were apparently ignorant of the oriental tongues, the account which they give of the words thence derived are often frivolous in the extreme. It is neceſſary to juſtify this aſſertion by a few examples. Αιμασια, *a hedge or fence,* occurs in Theocritus, Idyl. i. 47, and the ſcholiaſt derives it from ἁιμα, blood; becauſe thoſe who paſs through ſuch a fence are made to bleed. This derivation, nugatory as it appears, is adopted by Hederic in his lexicon: whereas its origin is the Hebrew אמץ, *amez, to ſtrengthen, to ſecure,* and thence applied to a *hedge,* which by ſurrounding defends a place. On the ſame principle κηπος, *a garden,* the origin of which neither Hederic nor any of the ancient ſcholiaſts, we believe, have attempted to unfold, is borrowed from קוף, *koph,* to ſurround: hence the term denoted a place ſurrounded or ſecured as a garden is. Lennep indeed derives it from καπος, *breath,* a word quite foreign to the purpoſe. The word βουριια, which occurs in Theocritus, Idyl. vii. 10, is thus explained by the ſcholiaſt; πηγη εν Κῳ, απο του βου μοριου, και του ῥεω η ὁτι βοος ῥινι παραπλησιος, *i. e.* a fountain in Cos, from the particle βου (large), and ῥεω, to flow, or becauſe it reſembles the noſtrils of an ox; whereas βουριια is evidently the Hebrew באר, *baar,* or בור, *bur,* a fountain. The Greek ſcholia, annexed to every author, abound with ſuch puerilities as the above; nor is the "Etymologicum Magnum" to be excepted, though the Greek lexicographers have ſought for no better or more rational guides in their enquiries after the origin of the words which they explain.

Hemſteruſe, Valckenaer, Ruhnken, Villoiſon, Lennep, Scheid, are indeed juſtly celebrated among modern critics for their reſearches into the origin and meaning of the Greek tongue. Their theories contain many valuable obſervations on the analogy by which that language grew from comparatively few radicals to its preſent complicated form; but their ſyſtem of etymologies appear to us, for the moſt part, fanciful and erroneous; becauſe in no inſtance, or at leaſt in very few inſtances, have they ſought the Greek terms in the languages of the Eaſt, whence aſſuredly they had been derived. Hemſteruſe derives θεος, Deus, from the verb θεω, to run, to diſpoſe; while its real origin, in our opinion, is the Hebrew and Arabic צאה, *zae,* pronounced in the latter language *dhao,* to ſhine. The Chaldeans repreſented the Supreme Good under the figure of light; and to this repreſentation the ſacred writer ſeems to allude, when he ſays that God is light. The ſame writer deduces οβριμος, *ſtrong,* from βριθυς; while its ſource is אבר, *abur,* to be ſtrong. From the ſame origin he ſuppoſes πριν or πρι, *before,* to have flowed, though it ſeems to point to the Hebrew פרע, *phra,* which in Arabic means the head or root of a family, and hence it came to ſignify origin or priority in the form of πρι: hence *prior* or *prius* in Latin.

Scheid derives τερας, an omen, from τερω, *tero,* to wear, becauſe omens, ſays he, obterant, quaſi, ſive ſtupore percellant, enecent que mortales. But the word is the Hebrew טיר, *teer,* a bird, divination, which was taken from birds. The ſame writer will have τενδω, or τενθω, *to eat,* to have come from τεινω, or τειω, to ſtretch, though far more naturally it points to the Perſian דנד, *dand,* dens, *a tooth;* and hence τενδω primarily meant, to cut with the teeth. The Hebrew צהר, *zer,* to ſhine, to ſcorch, gave birth to ξηρος, aridus; but Villoiſon fooliſhly derives it from ξεω, radere. The ſame critic as wiſely traces ξυλον to the ſame root, becauſe, ſays he, lignum ſit ad radendum aptum. But its origin is evidently אשר, a grove, hence αξυλος, wood, and by dropping the firſt vowel ξυλον, and by tranſpoſition αλσος, nemus.

cernus. Οπταω, *aſſo*, ab, οπτος, aſſus, ſays Scheid, quod ab οπτω, quod idem atque οκω, et ακω, *pungo pungendo figo.* But the parent word is אפה, to roaſt; and οπταω, to fry, ἁπτω, to kindle, εψω, to boil, are, with all their compounds, but the common offspring of this term. We ſhall only add one inſtance more from the Etymologicum of Lennep. Ορχεομαι ſalto ab ορω. Dici videtur a motu in altum. Componendum quoque eſt cum ερχομαι (venire.) Ab ορω factum ex ορεω, hinc ορεγω, *cum contentione moveo*, pec. in altum: unde facillima via ad ορεχω; ορχω, ορχεω. Rectiſſime igitur Etymol. c. 634, 52, παρα το ορεγω, και εκτεινειν τας χειρας—και ορχεισθαι Α[illegible], [illegible] ον. Unum tamen addidiſſe liceat, ſecundum analogiæ leges, ab ορχος (derivata voce verbi ορχω) pp. repetendum fuiſſe ορχεω, cujus Media forma eſt ορχεομαι.

This paragraph is a fair ſpecimen of the manner in which theſe etymologiſts have, by certain analogies, founded on their own fancies rather than on the real ſtructure of the Greek tongue, yoked together under one common root words the moſt foreign to each other.

The verb ορεχω did not come from ορω, or ορεω, but from ערג, *areg*, to deſire, or to ſtretch to an object, when deſired. From the ſame origin are derived ορεγνυμι, ορεχθεω, ορεχθω, ορεκτιαω, ορειχνομαι, ορεγνυκομαι, οργαω, and αργαω, all of which are but different modifications of the ſame primitive words by different people who uſed the ſame tongue. On the other hand, ερχομαι, to come or go, originated in ארח, *arukh*, or ארך, *arek*, to travail, prolong, extend. On the other hand ορχος, which means a row of plants, or the order in which any thing is done, is from the Hebrew ערך, *arek*, to arrange or place in order. From ορχος, arrangement, meaſure, rhythm, came the verb ορχεω, or ορχεομαι, to move to the ſounds of muſic in a dance or to battle. The movements in a dance and in war appear to have been regulated by the ſame meaſures; and hence dancers and warriors had the ſame names applied to them. *Mars* being called ορχηστης, as the author of the Etymologicum writes, ὡς προς πολεμον ευκινητος. Hence, too, a leader, *i. e.* one who put the men in order of battle, was called ορχαμος; and, moreover, πρυλις, which denoted a ſpecies of dance, came in Latin to ſignify prælium. Such learning, acuteneſs, and diligence as were poſſeſſed by Hemſteruſe, and the celebrated men abovementioned of his ſchool, however perverſe, could not altogether have been miſapplied. Their labours, therefore, muſt preſent ſome inſtances of juſt etymology, but their ſyſtem, upon the whole, appears to us both fanciful and erroneous, and calculated more to perplex their readers than to furniſh them with ſolid information.

Etymology, as it may ſerve to aſcertain the primary ſenſe of a word, to unfold a general principle in the formation of language, to exemplify the manner in which philoſophical notions, political occurrences, and religious inſtitutions influence the mind and give birth to new modes of ſpeech, is a ſubject of rational and uſeful enquiry. In this enlightened view it blends itſelf with the hiſtory of philoſophy, of politics, and of religion, with the ſtructure of the human frame, and even with the theory of the human mind. Connected with any or with all of theſe purpoſes, none but the uninformed will neglect or decry this branch of philology as vain and uſeleſs; and without ſuch connection none but pedants will purſue or extol it as worthy of attention. As the Greek originated in the Aſiatic languages, a knowledge of theſe languages to a certain extent is abſolutely neceſſary, to form a rational and competent etymologiſt in the dialects of Greece: and many paſſages muſt exiſt in the Greek writers, eſpecially the more ancient poets, which can be underſtood only by light reflected from the Eaſt. It will not be foreign to our purpoſe to illuſtrate this poſition by a few examples. The firſt we ſelect occurs in Homer's Iliad, ii. 815:—

> Εστι δε τις προπαροιθε πολεως αιπεια κολωνη
> Εν πεδιω απανευθε, περιδρομος ενθα και ενθα,
> Την ητοι ανδρες Βατιειαν κικλησκουσι,
> Αθανατοι δε τε σημα πολυσκαρθμοιο Μυριννης.

Of this paſſage the following is a literal verſion: *There exiſts apart in the plain, in the front of the city, (namely* Troy*) a lofty mount, acceſſible by a circular aſcent. This men call* Batieia; *but the Immortals the tomb of far-ſounding Myrinne.*

The language of the Trojans, though a dialect of the Greek, was, we may well ſuppoſe, from their ſituation, mixed by an influx of Aſiatic terms. Of this claſs is Βατιεια, which in Hebrew is בית, *beit*, and means an *abode.* In Iſaiah, xiv. 18, and Job, iii. 15, it ſignifies the laſt home of man. The term here occurs in the Syriac form ביתא, *bateea*, and has the ſenſe which it bears in the Jewiſh ſcriptures. Hence we diſcover the meaning of the paſſage, which has eſcaped the knowledge of the critics, ancient and modern. Βατιεια means the ſame thing with σημα, and the clauſe, πολυσκαρθμοιο Μυριννης, is to be connected with the former as well as with the latter; and the import of the phraſe is, *Men call it (Batieia) the grave, and the Immortals the tomb, of Myrinnes.* By *men* Homer meant the vulgar people of Troy; by the *Immortals* he intended the poliſhed Greeks. Here we ſee the partiality or rather the pride of the poet reſpecting his language and countrymen. The phraſe is purely oriental. The elegant Shanſcrit is ſtyled *Daeb Nagoree*, writings of the Immortals. Conformably to the ſame lofty figure, Homer calls Greek, from its ſuperior poliſh, *the language of the immortal gods*, while he characterizes the dialect of Troy, from its barbarity and rudeneſs, the *language of men.*

The explanation which the critics have given of Βατιεια is various, each rendering it more uncertain and improbable. Heſychius explains it to be πολις Τρωικη. Others derive the term from βαω, or βαινω, to go; and others again from βατος, *bramble*, becauſe, as Heyne ſays, collis ſentibus obductus eſſe potuit. As the commentators did not know the origin or meaning of the word, it is not to be expected that they ſhould underſtand the ſingular phraſeology grounded upon the uſe of it. Euſtathius's account of it is, το μεν ὁλως κρειττον των ονοματων θεοις διδωσιν ὁ ποιητης; *the poet aſcribes the beſt name to the gods.* The ſcholiaſt ſays, τον μεν πρωγενεστερον ονομα εις θεους αναφερει ὁ ποιητης, το δε μεταγενεστερον εις ανθρωπους; *the poet refers the more ancient name to the gods; the more recent name to men*; which cannot be true: for Βατιεια is at leaſt equally ancient with σημα. Clarke comes nearer the truth, who ſuppoſes the language of the *Immortals* to mean the language of the learned; and this great critic would have ſeen that Homer intended to contraſt not the language of the learned with the vulgar Greek, but the poliſhed language of the Greeks with the barbarous dialect of the Trojans, if he had been aware that βατιεια, in this dialect, meant a *tomb*, or the ſame thing with σημα. We ſhall only obſerve that this word exiſts in Celtic, and bears the ſame ſignification—*bedd, a grave.*

The next paſſage in which the uſe of the Oriental tongues ſerves to illuſtrate obſcurities in Greek authors, we ſhall ſelect from the Agamemnon of Æſchylus. On this paragraph much has been written, and written in vain by the critics. *Clytemneſtra*, the lady Macbeth of ancient days, boaſts in it of her fidelity, during the abſence of her lord, and the joy with which ſhe would receive him on his return.

> Ουδε οιδα τερψιν, ουδε επιψογον φατιν,
> Αλλου προς ανδρος μαλλον η χαλκου βαφας.

The lines are thus rendered in the elegant and poetical verſion of Mr. Potter:

——— Never knew I pleaſure
In the blamed converſe of another man,
More than the virgin metal in the mines
Knows an adulterate and debaſing mixture.

On this paſſage the author has the following note: Paw honeſtly ſays, "aliquid ſubeſt quod non intelligo." Mr. Heath diſapproves the alluſion, though he thinks it a proverbial expreſſion, the grace of which is loſt on our ignorance, and ſays, "quod nos non videmus alius olim forſan videbit."—In the old Perſian called the *Pehlevi*, the firſt principle of things was called באב : and though ſuppoſed to be fire by the diſciples of Zoroaſter, the term is a modification of אב, *ab*, water, which the Arabians maintained to be the original element. With the notion that water is the primary matter, the early Greek philoſophers appear to have borrowed the term. Hence βαπτω, *to plunge*, (which Lennep abſurdly deduces from βαω): hence too βαφη, *immerſion;* and the phraſe χαλκου βαφη is a metaphor for a *ſtab* or *wound*, it being produced by a weapon plunged into the body as into water. The ſentiment which the words convey to the herald, whom Clytemneſtra addreſſed, is to this effect, *I know no pleaſure with any man, and feel no more the ſting of calumny, than the point of ſteel.* But the language is ſtudiouſly equivocal; and in this peculiarity conſiſted at once the ſkill and the obſcurity of it. While the queen *appeared* to expreſs the above meaning, ſhe in reality expreſſed quite the reverſe. I know no greater pleaſure, though no report more diſgraceful, than a ſteel plunged in him, (namely Agamemnon,) by another huſband. This artful equivocation ariſes from the manner in which the clauſe αλλου προς ανδρος is connected. If taken with τερψιν the lines convey the *firſt* ſenſe; but with χαλκου βαφας, they convey the *laſt*.

For this interpretation we have the beſt authority, namely that of the *Chorus*, who were preſent: who, perceiving that the herald was miſled by the artful ambiguity of the words, hints at their true ſignification as ſoon as the queen withdrew from the ſtage.

Αυτη μεν ὁυτως ειπε μανθανοντι σοι
Τοροισιν ἑρμηνευσιν ευπρεπως λογον.

Which may be thus renderd: *This woman hath told thee learning (thee who haſt yet to learn,) what ſhe is, a tale which diſcerning interpreters perceive to be very becoming,—well to become her character and views.* Here τοροισιν ἑρμηνευσιν depend on ευπρεπως; and the Chorus intimate, that her words, underſtood, as they ſeem to have been by the herald, were falſe and unbecoming, but ſtrictly true and appropriate in the ſenſe in which *they*, who knew the woman better, had reaſon to regard them. Taken in the firſt ſenſe, the metaphor χαλκου βαφας is too violent for the ſimplicity of the ſentiment; and the falſehood, moreover, is ſo glaring as to claſs the queen with the baſeſt of deceivers, without a trait of that maſculine intrepidity and elevated ardour with which ſhe preſſed to the object of her deſire. In the latter it exactly ſuits the dark ambiguity of prophetic language: and the boldneſs of it is in uniſon with that vehemence and glow of pleaſure, with which ſhe anticipated the plunging of the weapon in the boſom of her huſband. For theſe reaſons the Chorus juſtly pronounce her language ευπρεπες, as at once expreſſive of her true feelings, her artifice, and her intrepidity.

Lycophron, who flouriſhed under Ptolemy Philadelphus, is known to have ſtudiouſly affected the uſe of hard and obſcure terms; which, from their antiquity, muſt demand the attention of Aſiatic ſcholars. In his *Caſſandra*, the only remains of his voluminous productions, occur theſe lines:

Τραμπις τ' εχινος και Φερεκλειοι ποδες
Διττους σταθμους ἆξει, κ'απι Γυθειου πλακας;
Εν αἷσι προς κινουρα, καμπυλας σχασας
Ηιονας [illegible], εκτορας πλημμυριδος.

They contain a prophetic addreſs to Paris, now commencing his expedition for the rape of Helen, and may thus be literally rendered: —*The ſhip and feet of Pherecleus will bear thee to the two ports and coaſts of Gythium, having in theſe fixed to the rocks the crooked teeth of the pine, Hectors (i.e. ſuſtainers,) of the flood.* Pherecleus as an artiſt conſtructed the ſhip, and as a ſoothſayer, conſulted the gods, and endeavoured to conciliate them to the projected expedition. As ſuch, he was naturally led to give the veſſel the name of τραμπις, which with the Greek termination is the Chaldean and Phœnician term for the tutelary gods, תרפים, *tarpim*, or *trapim*. The ſcholiaſt ſays, it is the name of *a foreign ſhip;* and in this he is followed by Heſychius. It was certainly uſual to carve the images of the gods on the ſhip, which they were ſuppoſed to protect; and to them the ſailors fled in ſeaſons of danger. (See Hor. i. 14.) The figures, which at this day are often framed in the forepart of the ſhip, are but the remains of the ſame cuſtom. The practice, no doubt, originated with the Phœnicians: and it was natural for them to call their ſhip by the name of thoſe gods which were ſuppoſed to preſerve them. The rudders, the oars, the ſails, by which the veſſel was moved, are here affectedly called the *feet* of Pherecleus, he being the author of them. Of the derivation of the term the ſcholiaſt and Heſychius appear equally ignorant, and the whole of this paſſage is a ſtriking inſtance how incompetent the ancient commentators were to explain in many places the terms of the Greek tongue.

The ancients had ſtatues of their gods erected before their doors, and in the entrance of their harbours. Theſe received the ſalutations of ſtrangers and paſſengers. Lucretius mentions this cuſtom in his firſt book. Hence the doors and ports received the name of σαλαμβαι, as being places where the gods were *ſaluted*, from the Arabic שלאם, *ſalaam*, ſalutation. The account which the ſcholiaſt gives of this term is ridiculous: σαλαμβαι δε αἱ θυραι λεγονται, παρα το ἐν σαλῳ βαινειν. The explanation of Heſychius is more rational, though not the true one; σαλαμβη ἡ οπη δι ἧς το σελας βαινει. This is a fair ſpecimen of the manner in which the Greek words, derived from the Eaſt, are explained in the old gloſſaries. But farther, πλακας, *coaſts*, is the Hebrew פלג, *paleg*, or *plag*, (the vowels being arbitrary, and not exiſting but as included in the conſonants of the original,) and ſignifies to divide, and thence as a noun any thing divided, ſuch as portions of the land and ſea. From the ſame original is derived πελαγος, as ſerving to divide the earth into diſtinct territories: hence too, the Latin *plaga*, a clime or region. Finally, the unuſual term κινουρα originated in the Perſian *kinaar*, an extremity or limit which, as the limits of a river came hence to ſignify its *banks;* as the limits of the ſea its *ſhores*, or the *rocks* lining them. The limits of a door are its poſts; and hence the Celtic word *kynnor*, the door poſts; and probably from the ſame ſource, on account of their remoteneſs, has been derived the appellation aſſigned to the Canary Iſlands.

The attempts of Paris, under the auſpices of Pherecleus, to appeaſe or conciliate the gods, are alluded to by Horace, lib. i. 15. who appears to have had the paſſage of Lycophron in his view. Pherecleus, the firſt adviſer, perhaps, of the expedition, is repreſented by Homer as properly puniſhed; for he received an ignominious death from the hand of Merion. The poet adds, Il. v. 65. επει ουτι θεων εκθεσφατα ηδη, ſince he did not at all know the decrees of the gods. To ſay that Pherecleus did not poſſeſs this knowledge, appears not only a proſaic, but an unneceſſary ſaying: for who is the man that is acquainted with the divine decrees, while yet unfulfilled? But when it is conſidered that Pherecleus had *pretended* to be ſo knowing, and probably predicted ultimate ſucceſs, while the event turned out very different from his predictions, there is much propriety and even point in the remark; ſince it holds forth the *diviner* as a *deceiver*, who by his impoſtures brought ruin upon himſelf and his country. From this we may conclude, that the beauties of Homer, who confines himſelf beyond any other poet to general nature, yet in many inſtances depend upon circumſtances unknown to, or unobſerved by modern readers.

The prevailing taſte for oriental literature promiſes to contribute much to the improvement of philology. And when claſſic ſcholars ſhall engage with due attention in this purſuit, the more ancient Greek writings will ſhare in the general benefit, by the light reflected upon them from the Eaſt. The derivation of the Greek from the oriental tongues, the frequent uſe of terms which Homer, Heſiod, Lycophron, and others have adopted in their primary ſignifications, have occaſioned difficulties which a critic, however able, but verſed only in Greek and Roman authors, is hardly able to ſolve. Theſe difficulties, inſtead of being explained, have been gloſſed over by the futile etymologies of the ancient ſcholiaſts and lexicographers: and they can be properly felt and ſucceſsfully removed only by thoſe who have extended their ſtudy from the elegant language of the Greeks, to the no leſs poliſhed languages of Perſia, Arabia, and Judea. Of this poſition the examples above cited afford ſufficient illuſtration: and they are, it is hoped, too curious, new, and ſolid, not to be undeſerving of a place in a dictionary of ſcience.

In the laſt place, the derivation of the Greek from the ancient languages of the Eaſt, will account for the origin of the much diſputed *digamma*. In theſe tongues gutturals abounded, which, like other conſonants, contained in themſelves the vowel neceſſary to their pronunciation. But it is the tendency of every guttural, when become habitual, to ſoften down, in the rapidity of utterance, into a mere aſpirate, till it at length vaniſhes. Thus *cornu* has degenerated into *horn*; χαμος, into *humus*, earth, and into *homo*, a creature of earth, man. Thus alſo the Hebrew חי (χι,) which ſignifies *life*, *ſoul*, *ſelf*, appeared in Greek in the form of ἑυ, ὁι, ἑ. Moreover כבד, *kabád*, a liver, gave birth to ἥπατ-ος. This word retains an unqueſtionable mark of its derivation, for it has the form כבד, *kabad*, or, כבר, *kabar*: and this variation has been transfuſed into the Greek ἧπαρ and ἥπατ-ος. Hence we obtain the origin of the aſpirate placed over a vowel. It was originally a guttural, which loſing its power as a conſonant left the included vowel behind, with an inverted comma above, to perpetuate that part of the letter which fell into diſuſe.

The guttural, when ſoftened into an aſpirate, is apt to be dilated into a long vowel. Hence the reaſon why η, in the ancient Greek, ſeems to have been accompanied by an aſpirate, as in ἧπαρ. On the ſame principle that a guttural ſoftens into an aſpirate, the aſpirate often melts into a gentle breathing, or becomes in pronunciation quite quieſcent, as the Latin *honor* and *honeſtus* become in Engliſh *honour* and *honeſt*, the *h* being mute. On the ſame principle too *gh* became ſilent in our tongue, as in *taught*, *ſought*. So in the Greek חאן, *khaan*, a king, has degenerated into ανασσω, which Homer pronounced ϝανασσω. This leads us to remark, that the aſpirate, inſtead of vaniſhing, was changed into a labial letter *w*, *v*, *b*, *f*, or ϝ. Thus laugh, cough, which are ſtill ſtrong guttural ſounds among our northern neighbours, are ſounded *laff*, *coff*, among us. Thus alſo in Greek, what was at firſt written χανασσω, was pronounced ϝανασσω; and the words ἑυ, ἑι, ἑ, were ſounded *wou*, *woy*, *we*, or fou, foi, fe.

But the digamma did not always originate in a guttural, but ſometimes in conſonants allied to our *w* or *y*. Thus from ידע, *yido*, is derived the Greek ειδω, which in Homer is ſounded *wido*, becauſe the original is *yido*, hence the Latin *video*. So again fron יין, *yin*, is taken οινος, *wine*, ſounded *winos*: hence *vinum*, and *wine*.

We have already obſerved, that in Hebrew every conſonant contained in itſelf the vowel neceſſary to its pronunciation. This vowel the Greeks detached and gave it a ſeparate exiſtence, by ſubjoining it to the concomitant conſonant. And as the Hebrews ſeem at firſt to have ſounded every conſonant, thus dividing each word into as many ſyllables as it had of conſonants; and as they farther ſeem to have uſed vowels only in conjunction with conſonants, and to have conſidered them as unfit to be employed alone and independent, ſo the Greeks, in imitation of them, uſed at firſt only ſhort vowels: they next adopted the long or compound vowels η and ω; but ſtill avoided the diphthongs, and when any two vowels concurred, they converted the firſt of them into a labial conſonant. Thus, λαμπετοωντι, was ſounded not *lampetoonti*, but lampetowonti, or *lampetovonti*; and μουσαων, pronounced *mouſawon*, or *mouſavon*; ειπω, *wipo*.

This letter is called *digamma*, becauſe it has the form of two *gammas*, one upon another like our capital F, and alſo called *Æolic*, as ſuppoſed to belong excluſively to the *Æolic* dialect. But this account of it proves, that it did not belong, as Dr. Bentley and others have ſuppoſed, to the Æolic dialect only, but to all the dialects of Greece, in their more ancient mode of pronunciation. It follows alſo that the univerſal opinion of the learned, who ſay that the *digamma* at *firſt* prevailed, and was afterwards ſucceeded by the *aſpirate*, is the reverſe of the truth. For the true ſtate of the caſe is, that gutturals at firſt prevailed; theſe ſoftened into mere aſpirates; and theſe again were changed for a more eaſy and agreeable letter, which being ſimply a labial was diverſified by different people into *y*, *w*, *v*, ϝ, *b*, or *f*. But the digamma, it will be ſaid, is to be found only in Homer, by far the moſt *ancient* writer of Greece, while the aſpirate is in all the more *recent* authors. The anſwer is this: the uſe of the aſpirate obtained in the written language, and was, therefore, leſs ſuſceptible of corruption. On the other hand, that of the digamma prevailed in pronunciation, which was more liable to change, and to deviate from the original terms. Homer, we may naturally ſuppoſe, adopted the firſt in compoſing and *writing* his poems, and the laſt in *reciting* them to the people. The written form, we may preſume, was at firſt uſed but little, but prevailed by degrees; while the peculiarities of pronunciation in their turn began to decline. The language, as written by Homer, at length became faſhionable in the converſation of poliſhed people, and the aſpirate, being thus triumphant in the daily converſe of learned men, would of courſe, in their writings, triumph over oral and temporal corruptions.

The change of a guttural into an aſpirate, or into a long vowel, or into a labial letter called the *digamma*, is not peculiar to any one language, but is founded on the ſtructure of the organs of ſpeech; and inſtances of it prevail in all languages, both ancient and modern.

The preſervation of the aſpirate in the written language of

Homer, while the *digamma* was uſed in reciting them, is a proof (if a proof be wanting) that Homer did actually uſe a *written* language, and that his works were preſerved by a written language: otherwiſe the aſpirate would have been loſt, and the *digamma* alone would have prevailed in all the Greek authors who ſucceeded that celebrated bard. If an editor of Homer in modern days would inſert the digamma, he would corrupt the original orthography of Homer, and ſubſtitute in the room of the original characters the corruptions of pronunciation.

We ſhall now make ſome obſervations on the leading parts of ſpeech, which may ſerve to unfold the peculiar nature and amazing extent of this language. As gender is the diſtinction of ſex, there cannot in ſtrictneſs be in any language more than *two* genders, maſculine and feminine; nouns expreſſing inanimate objects, or things without life, being in a philoſophical ſenſe *neuter* or *neither* gender. But neuter nouns had by analogy aſſigned them the terminations of maſculine and feminine nouns; and unfortunately for Greek, and the other European languages affected by it, the termination became ſoon regarded as an index of the gender, without any reference to the meaning. Thus nouns deſignating females ended in α or η; and for this reaſon the names of inanimate things, and alſo adjectives, having the ſame ending, are ſaid to be *feminine*. For the ſame reaſon nouns in ος or ης, though meaning things without life, are generally maſculine, becauſe theſe happened to be the predominant terminations of the names of males. There are, therefore, in this language two principles which regulate the gender of nouns, the ſignification and the termination: the former aſcertaining the gender of living things, or things whoſe ſex it is of importance to diſtinguiſh, the latter that of inanimate objects. There is, however, a third principle, on which is founded the diſtinction of gender, we mean the analogy which inanimate objects ſometimes have to living creatures. There are ſome terminations common to males and females, and theſe afford ſuch analogy an opportunity to operate. Thus λογος, reaſon, though expreſſive of what is neither male nor female, is made maſculine, as ſignifying the commanding and the moſt excellent faculty of the human mind; whereas ὕδωρ, *away*, from its affinity to γη, the earth, or from the paſſive nature of its ſignification, a characteriſtic more of the female than of the male, is made feminine. That this analogy is not fanciful might be proved by many inſtances. In Ariſtophanes βατος is maſculine; but Theocritus (Idyl. i. 132.) in repreſenting it as producing *violet*, makes it feminine. This affinity to the female ſex is the reaſon why *arbor*, with the ſpecific names of trees in *us*, are always feminine, though the termination is decidedly maſculine. In caſes where the termination abſolutely belongs to the names of males or females, this principle of *analogy* neceſſarily gives way to the termination. Thus, becauſe η final is invariably appropriated to feminine nouns, θαλασση, *the ſea*, is feminine: on the other hand, χρονος, *time*, is maſculine, from its termination as well as from analogy.

Nouns and verbs in Greek have a *dual number* to expreſs two things, or ſuch things as are in pairs, as hands, eyes, feet. The uſe of the dual occurs frequently in the poets, though not peculiar to them, nor always obſerved by them, when ſpeaking of two objects. The dual number is by no means neceſſary in language, though it may enable the Greek to expreſs the number two or pairs with more emphaſis and preciſion. It was, therefore, rejected by the Æolians and by the Latins, who derived their tongue from the Æolic dialect. The ſeventy tranſlators, moreover, have rejected the uſe of the dual number, and in this they have been followed by the writers of the New Teſtament and the Greek fathers.

Caſes have been defined by all modern grammarians to be *changes* in the termination of nouns; but the name πτωσις, in Greek expreſſive of caſes, clearly ſhews that this is not the primary meaning of a caſe. For πτωσις means *a fall*, and, from ſignifying *a fall*, it came to ſignify the place in which a noun fails in a ſentence. The idea, then, which a caſe at firſt expreſſed is the *poſition* of a noun in a ſentence, and by that poſition expreſſing the relation of one word to another. Thus, if a noun denoted the *direct* ſubject of a propoſition or diſcourſe, it is ſaid to be in the *right caſe*, πτωσις ορθη, *i. e.* the direct or ſtraight poſition; but if a noun expreſs an object or quality *indirectly*, it is ſaid to be in an *oblique poſition*, πτωσις πλαγια, and this deviation from a direct to an indirect poſition, as the ſubject of diſcourſe, is in the language of grammarians farther called κλισις, declenſion. Farther, caſes expreſs the relation of things in motion or action, and the relations neceſſary for the purpoſes of language are chiefly the following: the relation of *cauſe*, the relation of *effect*, the relation of *beginning*, the relation of *medium* or *inſtrument*, and the relation of *end*. A noun denoting the relation of cauſe, *i. e.* denoting the agent of an active or the ſubject of a neuter or connecting verb, is in the *nominative*; that of effect in the *accuſative*; that of beginning in the *genitive*; that of medium or inſtrument in the *ablative*; and that of end in the *dative*. The nominative alone is called the *right* or direct caſe, the reſt are all deemed *oblique* caſes; though the accuſative, as expreſſing a direct part of a propoſition, might more properly be called a right, than an oblique caſe.

Moreover, the relations of bodies in motion or action were at firſt expreſſed by *prepoſitions*: and as our ideas of relation ariſe from the things related, and which ſucceeded them in their formation, prepoſitions ſhould, and probably did, in the early uſe of language come after, inſtead of going before the nouns which they governed. In conſequence of this arrangement, they combined into one word with the final ſyllables of the connected noun, and thus ſerved to give it a diverſity of terminations. Hence the origin of caſes in the ſenſe in which caſes have hitherto been underſtood by modern grammarians. It is worthy of remark, before we quit this ſubject, that the nominative, as expreſſing *cauſe*, has a cloſe affinity to the genitive, which means beginning. But the former fixes the attention on the noun, as an *agent* or a cauſe in action: while the latter holds forth its noun as the *ſource* or *beginning* of motion. The beginning of a thing is often the author and owner of that thing: hence the genitive has the ſecondary ſenſe of *poſſeſſion*. On the other hand, the accuſative is nearly allied in ſenſe to the dative; but the former is not uſed in its ſtrict and original ſignification, unleſs it denotes an *effect*, or the thing in which *action* terminates; while the latter, in ſtrict propriety, marks the end to which *motion* points, and in which it terminates. The genitive ſtands oppoſed to the dative, as beginning to the end, like the oppoſite points of a right line; while the ablative expreſſes the medium or inſtrumentality of the motion by which that line is generated. The ablative caſe therefore denotes one of the moſt important and diſtinct relations in language, and yet the Greek, with all its boaſted copiouſneſs and preciſion, has not a diſtinct termination to expreſs this caſe, but denotes it ſometimes by the genitive, and at others by the dative, with or without a prepoſition. Finally inanimate things only move after they are put in motion, or act as they are acted upon. This is probably the reaſon why neuter nouns in Greek have no termination to expreſs cauſe, diſtinct from that which marks effect, that is, why the nominative and the accuſative of Greek neuter nouns are always the ſame.

A multitude of nouns in all languages expreſs the abſtract ideas of action, and conſequently are derived from verbs, as ſubſequent to verbs in their formation. Our ideas moreover of the perſons, the characters, the offices of men, are derived from the ſame ſources; and from verbs are derived the nouns which expreſs thoſe perſons, characters, and offices.

The name of the *actor* is derived from the correſponding verb by adding της, ης, ας, ευς; as μαθεω, *to learn*, μαθητης the perſon that learns, a learner; ιχνευω, *to ſeek*, ιχνευτης; μαστευω, *to enquire*, μαστηρ, *the perſon who enquires*; σπειρω, *to ſow*; σπορευς, *a ſower*.

Nouns expreſſing the action of the verb abſtractedly conſidered, or the effect of that action, are derived from the correſponding verbs by adding σις in the room of the final ω; as τερπ-ω, *to delight*, τερπσις; τερψις, *delight*, *the act of delighting*; τεκ-ω, *to produce*; τεκσις, τεξις, *the act of producing, production*; κριν-ω, *to judge*, κρινσις, κρισις, *judgment*. Hence it is evident that verbs in πω or πτω, βω, φω, muſt have their correſponding nouns in ψις: thoſe in κω, γω, χω, and thoſe in σσω (for γω) in ξις; and thoſe in ζω and σσω (for ζω) in σις. The penultimate vowels α and ε are changed into η, and ο into ω: as μαθεω, *to learn*; μαθησις, *inſtruction*; ορθοω, *to rectify*; ορθωσις, *rectitude*.

Other verbs are changed into abſtract nouns by changing the laſt ſyllable into μα or μος, or ſimply into η, the penultimate ε being changed into ο after the analogy of the perfect middle; as βλεπω, *to ſee*; βλεπμα, βλεμμα, *a ſight*; κριν-ω, κρινμα, κριμα, *judgment*; τρωω for τραυ-ω, *to pierce*; τραυμα, *a wound*; ἁρπαζω, *to plunder*; ἁρπασμος, *plunder*; ὁριζω, *to define*; ὁρισμος, *definition*; φθειρω, *to corrupt*; φθορα, *corruption*; σπειρω, *to ſow*; σπορα, *ſeed*.

Adjectives are converted into abſtract nouns by changing the laſt ſyllable into της, or into υνη, or into ας, or into ια; ποιος, *qualis, ſuch*; ποιοτης, *quality*; κακος, *baſe*; κακοτης, *baſeneſs*; μονος, *alone*, or *one*; μονας, *the number one, monad*; δυω, *two*; δυας, *the number two*; αληθης, *true*; αληθεια, *truth*; δοκιμος, *approved*; δοκιμασια, *approbation*.

Adjectives, being the names of qualities, are taken from the names of the objects to which thoſe qualities in a prominent manner belong; as ονος, *an aſs*; ονοτος, *contemptible*; ανεμος, *wind*; ανεμοεις, *windy*; ανεμωλιος, *empty, like the wind*. But adjectives are derived from nouns by annexing to them the verbs expreſſive of ſimilitude, εικος, *like*; ειδος *reſemblance*; ειος, *ſuch, like*; as ανθρωπος, *a man*; ανθρωπικος, *man-like, manly*; ανθρωπειος for ανθρωπ-ιος, *man-like*; alſo ανθρωπωδης, for ανθρω-ποειδης, having the form of a man, manly. This compoſition is the origin of that claſs of nouns called *patronymics*. Πηλευς, Πηλειδης, one having the form of Peleus, *i. e.* the ſon of Peleus.

There are in Greek but two perſonal pronouns, that is, ſubſtitutes for nouns, or, as we have explained them in the article Grammar, numeral adjectives, aſſuming the character of nouns by aſſociation with the verb. Theſe are εγω, *I*; συ or τυ, *thou*; and they are evidently derived from the Hebrew אנכי, *ankee*, *I*, which in Greek is written in the various forms of εγω, εγων, εγωνη, ιωγα, ιωγγα; אתה, *ata*, and by dropping א, תה, *tau*, or the Æolic τυ: ὑ always expreſſes the ſubject or agent in one of the oblique caſes, and therefore, as not wanting, has not a nominative caſe. Its origin is the Hebrew חי, *khi*, *life*, *ſoul*, *ſelf*, which latter is the ſenſe of ὑ. Pronouns of the third perſon are only definitives or reſtrictive adjectives agreeing with the noun defined, expreſſed, or implied. The chief of theſe is ὁ, *the*, *he*, which very improperly has been called an *article*; whereas it is a *definitive* derived from the Hebrew ה, *ha*, which, as an abbreviation of הן, *en*, ſerves to direct the attention to an object, and thus to diſtinguiſh that object from all other things. Ὁς, *who*, αυτος, *the ſame*, ὁυτος, *this*, are but different modifications of ὁ. In ſpeaking briefly of the verb, we ſhall do little more than copy Mr. Jones's ſyſtem, as explained in that part of his Greek grammar where he treats of the origin of verbs. This ſyſtem is founded on the Hebrew tongue, in which all the varieties of mood, tenſe, number, and perſon ariſe from the combination of the perſonal pronouns with a radical noun or verb. Though a multitude of abſtract nouns are borrowed from verbs, yet all or moſt of the Greek verbs are nouns converted into verbs, by annexing to them the perſonal pronouns. His own words are: We acquire the ideas of action by reflecting on ourſelves, or obſerving others in certain circumſtances; and the moſt ſimple way which nature could at firſt ſuggeſt of expreſſing theſe ideas was to combine the name of the perſon or thing which acts with the perſon or thing acted upon. Thus οινος and εγω joined, and abbreviated, is οινοω: and this term would be ſufficient to expreſs *I drink wine*, though it originally meant only *wine I*: aſſociation ſupplying to the ſpeaker, and to the perſon addreſſed, the intermediate notion of *drinking*. From this account of the origin of verbs, he deduces three concluſions of importance to be obſerved. *Firſt*, verbs were originally the names of things; and thus received their characters as verbs from aſſociation. *Secondly*, that every verb conſiſts of a pronoun expreſſing an agent, and of a noun or the ſubſtitute of a noun expreſſing an object. *Thirdly*, that the terminations, ω, εις, ει, ετον, ομεν, ετε, ουσι, were originally the perſonal pronouns, and from theſe, with the changes which they underwent, have proceeded all the variations of mood, tenſe, number, perſon and voice.

The firſt perſon, ω, is a fragment of εγω; and by the ſame analogy that εγω becomes εμε, verbs in ω are changed into verbs in εμι; as ἱσταω, ἱσταεμι, *to place*, θεω, or τιθεω, τιθεεμι, *to fix*; δοω, or διδοω, διδοεμι, *to give*; κλυω, or κικλυω, κλυεμι, or κικλυεμι, *to hear*. The perſonal terminations of verbs in εμι are therefore but a modification of thoſe in ω, and conſequently a modification of the perſonal pronouns εμι, ες, ει, ετον, εμεν, ετι, εσι. On this principle the verbs in μι, which grammarians have hitherto divided into four diſtinct claſſes, are, according to Mr. Jones's theory, but one claſs, having each the ſame perſonal termination, and differing only by different modes of contraction; as ἱσταεμι, ἱστημι; τιθεεμι, τιθημι; διδοεμι, διδωμι; κικλυεμι, κικλυμι. This complex ſpecies of verbs is hence reduced into great ſimplicity, and the acquiſition of them rendered very eaſy. The firſt perſon optative, even of verbs in ω, conforms to the analogy of verbs in μι, τυπτοιμι, which originated in τυπτομι, though obſolete. From this ſource the Latins have derived the final *m*, amabam.

The ſecond perſon in Hebrew is ת, *tha*, or *ta*, a fragment of אתה, *ata*. Hence the Ionians formed this perſon in θα—οισθα, *thou knoweſt*; ησθα, *thou waſt*. The above fragment, conſiſting of *th* or *t* only, has been corrupted into ς. Hence the ſecond perſon in every tenſe of the active voice terminates in ς, with ε or α ſhort preceding. The ſubjunctives ι, υ, form no part of the original pronouns, but were inſerted, as is often the caſe, to lengthen the preceding vowel. The third pronoun in Hebrew is הוא, *hoe*, which is the parent of *he* in Engliſh, and in Greek of ὁ. This, with the ſubjunctive ι, forms the third perſon, τυπτει. To the original ὁ the Ionians added σι. Thus in verbs in μι, τιθεεσι, τιθησι, for τιθη, and in the ſubjunctive of verbs in ω, we meet with ελθησι for ελθη. In Shanſcrit, a language which has a great ſimilitude to the Greek, *ſu* or *ſuh* means *be*.

In Arabic the ordinal of *two* is *tan*. Hence the Greek dual τον or την, τυπτετον, or τυπτετην, *they two beat*. The perſonal termination in the plural are all formed from the ſingular. Thus εμι, by the analogy of the third declenſion, is εμες, and in this form it was uſed by the Doric, the moſt ancient dialect of Greece, τυπτομες, ετυψαμες. In the common tongue the final ς became corrupted into ν. The ſecond plural is the ſame in its origin with that of the ſingular *ta* or *te*, τυπτετε, and the third plural is the ſame with the third ſingular differently contracted, τιθεεσι τιθησι, *he places*, τιθεισι, *they place*. The third of verbs in ω is formed from the third of thoſe in μι, with the ſubjunctive υ annexed, τυπτεσι, τυπτευσι, which is the Æolic form, and hence in the common tongue, τυπτουσι. The vowel ε, not only in ſingle inſtances, but in whole claſſes of words, is changed into ο. Thus in the formation of nouns from verbs τεμνω, *to cut*, τομη, *a ſection*; in forming the perfect middle, πειθω, *to perſuade*, πεποιθα, and ſometimes the perfect active βρεχω, *to rain*, βεβροχα; in forming circumflex from other verbs, τρεμω, *to tremble*, τρομεω; by corruption in ſingle words οδοντες, εδοντες, *teeth*, γονυ, *genu*. On the ſame principle the Æolic ευσι became ουσι.

The perſonal terminations of the imperfect or paſt tenſe in μι, are εν, ες, ε, ετον, ετην, εμεν, ετε, εσαν; as τιθεεμι ετιθε-εν, διδο-εμι εδιδο-εν, ιστα-εμι ιστα-εν, κικλυ-εμι εκικλυ-εν. Theſe are alſo formed, according to Mr. Jones's theory, without the reduplication, θεεμι εθε-εν, δο-εμι εδο-εν, στα-εμι εστα-εν, κλυ-εμι εκλυ-εν. Theſe are hence contracted either with or without the reduplication; ετιθεεν ετιθην, εθεεν εθην, εδιδοεν εδιδουν, εδοεν εδων, εκικλυεν εκικλυν, εκλυεν εκλυν. By the converſion of ε into ο, on the principle above illuſtrated, the perſonal terminations of the verbs in μι, it was that εν, ες, &c. became ον, ες, ε, ετον, ετην, ομεν, ετε, οσαν. The firſt perſon ſingular in Hebrew is אני, *eni*, *I*. Hence the perſonal termination εν or ον. The third plural εσαν or οσαν, is the Perſian אישן, *eeſan*. Hence we read ηλθοσαν in verbs in ω, and ετιθεσαν in verbs in μι; but οσαν is contracted in the common tongue into ον; as ετυπτοσαν, ετυπτον.

The ſecond aoriſt is the ſame tenſe with the imperfect, and verbs of the imperfect differ from verbs of the ſecond aoriſt, not becauſe they expreſs different modifications of paſt time, but becauſe they came from different roots. Thus, from τυπτω and σπαιρω are derived the imperfect ετυπτον and εσπαιρον; while ετυπον and εσπαρον, in the ſecond aoriſt, have been deduced from the obſoletes τυπω and σπαρω; as is the ſignification, ſo are the terminations the ſame in both. The pluperfect has its perſonal terminations from the imperfect, by annexing the ſubjunctive ι in each perſon—εν, ες, ε, &c. ειν, εις, ει, &c. The characteriſtic of the firſt future is σ inſerted before the final ω of the preſent—τυπτω or τυπω, τυπσω τυψω, λεγω, λεγσω, λεξω. And what grammarians call the ſecond future, is no other than the firſt future, where, after a very general analogy, σ is dropped. Thus, βαδιζω, 1 fut. βαδισω, βαδιω; εκχεω, 1 fut. εκχεσω, εκχεω, *I will pour*; εξελαω, *to expel*, εξελασω, contracted εξελω. So τυπω, ſaid to be the ſecond future, is a contraction of τυπεσω, from the root τυπεω. And this obſervation holds in regard to all other verbs ſuppoſed to be the ſecond future, while, in fact, no ſuch tenſe exiſts.

The ſubjunctive mood is derived from the indicative, by changing ε into η, ο and ου into ω, and ſubſcribing ι where it occurs. It is thus formed, in every tenſe, through the active, the paſſive, and the middle voice. Thus, τυπτω, τυπτεις, &c. have given birth to τυπτω, τυπτης, &c.: ſo, in the firſt future, τυψω, τυψεις, τυψει, originated τυψω, τυψης, τυψη, which is not the firſt aoriſt, as is ſuppoſed by grammarians, but the firſt future, which is, indeed, proved by its ſignification, as well as by analogy: for, in all inſtances this ſenſe expreſſes *a future* time, not abſolutely ſo, but time future in regard to another verb connected with it in the ſentence. The optative has its tenſes, in general, derived from the correſponding tenſes in the indicative, by changing ε into ο: but the firſt perſon, as has been obſerved, is derived from verbs in μι; as, if τυπτεεμι, τυπτεις, τυπτοιμι, τυπτοις. The third plural, like the third ſingular, follows the analogy of verbs in μι—τυπτοιησαν, contracted τυπτοιεν; in the ſame manner as δοιησαν becomes δοιεν.

The imperative mood, originally in the firſt perſon, retained εν of the imperfect tenſe; as λαβεν, *let me receive*. Thence, dropping the final ν, it has, in the common tongue, the firſt perſon in ε—τυπτε. The pronoun τυ, which, in Perſian, is *to* added in the form of τω, conſtitutes the ſecond or third perſon—τυπτετω. And εσαν, contracted into σαν, forms the third plural—τυπτετωσαν, which, by dropping σα, is again abridged into τυπτετων, erroneouſly ſuppoſed to be the dual number. When a command is given, it is neceſſarily given in the preſent time, and it can be executed, not in the *paſt*, but in the *future*. It is impoſſible, therefore, in reaſon, that the imperative mood can have a *paſt* tenſe. Thus, τυπτε is the preſent imperative, or that of the ſecond future; and τυψον the firſt future, not the firſt aoriſt. In ſome of the dialects ι is ſubſtituted for the ſubjunctive vowel. On the other hand, the Ionians change ν, with or without its concomitant vowel, into α. Thus, in the imperfect, for ην, or εν, they uſed εα, *I was*: for the pluperfect ετετυφειν or ετετυφεν, ετετυφεα, which the Attics contracted into ετετυφη; and in the third perſon plural, of the paſſive form, for τυπτοιντο, they write τυπτοιατο, and for κεινται, κεαται. In the ſame manner τυψον, which is ſaid to be the firſt aoriſt, but which, in reality, is the firſt future, becomes, when τω is added, not τυψοντω, but τυψατω. From the imperative thus principally ending in ον, we obtain the attic third perſon plural in οντων—τυπτουντων, ποιουντων, which are contractions of ποιουντωσαν, τυπτοντωσαν, the firſt being ποιεεν or ποιουν, and τυπτον for τυπτεν. By the above Ionic analogy, we alſo obtain what is called the Æolic firſt aoriſt, τυψεια, which has the perſonal terminations of the firſt aoriſt indicative. It is thus changed from τυψειην or τυψοιην, uſed for τυψοιμι, in the ſame manner as φιλοιην is for φιλοιμι.

The infinitive is formed by adopting εν, or, as it is in Hebrew, εν—τυπτεν, and by ſubjoining ι, τυπτειν. In the perfect it has εναι, τετυφεναι; but in the firſt aoriſt ν is dropped —τυψαι, probably for τυψαναι, which, after the analogy of the perfect, would be τυψεναι. In the Ionic and Attic dialects, the infinitive, however, is formed from verbs in μι, though obſolete, τυπτεμι, τυπτεμεν; θεεμι, or θεμι, θεμεν; δοεμι or δομι, δομεν; ειμι, *I am*, ειμεν or εμμεν. To theſe, after the analogy of the perfect, is added αι—τυπτεμεναι, θεμεναι, δομεναι, εμμεναι.

The paſſive voice is formed by combining the ſubject of diſcourſe with the perſonal pronoun in the dative caſe—μοι, σοι, τοι. Thus οικοςμοι, *houſe for me*; οικοςσοι, *houſe for thee*; οικοςτοι, *houſe for him*. Theſe combinations, which by a ſlight change become οικιζομαι, οικιζεσαι, οικιζεται, came to convey the idea, *I have a houſe*, *thou haſt a houſe*, or *I am houſed*, *thou art houſed*. And this is the reaſon why the paſſive form in all authors have either an active or a paſſive ſignification, the context alone ſerving to aſcertain the ſenſe of the verb. The dual τον is made paſſive by changing τ into σθ—τυπτετον, τυπτεσθον and not τυπτεθον; and it is worthy of remark, that in the firſt perſon plural θ takes σ before it very frequently, as τυπτομεσθα for τυπτομεθα, and in the imperative σθι for θι.

As the perſonal pronoun, combined with the radical word to form the paſſive voice, was εμοι, the primary form of the verb muſt have been τυπτεμαι, and not τυπτομαι; and in the imperfect ετυπτεμην, and not ετυπτομην: but afterwards ε was changed into ο, as in other numerous inſtances. Hence the paſſive form of verbs in ω was originally the ſame with that of verbs in μι: and this form had only two ſenſes, μαι for the preſent, and μην for the paſt. The ſecond perſon ſingular is formed in the common tongue by dropping σ, and contracting the two ſucceeding vowels in every mood and tenſe. Thus τυπτεσαι, τυπτεαι, τυπτη; imperfect ετυπτεσο, ετυπτεο, ετυπτου; firſt aoriſt middle ετυψασο, ετυψαο, ετυψω; optative τυπτοισο, τυπτοιο: θεισο, θειο. The firſt future middle is derived from the firſt future active, by changing ο into ομαι, τυψομαι. The ſecond future middle is derived from τυπεσω, (which is from the obſolete τυπεω,) τυπεσομαι. This drops σ, and is contracted—τυπεομαι, τυπουμαι. Hence what is called the ſecond future is no other than the firſt future. The ſame obſolete radical has given riſe to the ſecond future paſſive, which is no other than the firſt future—τυπεω, τυπησω, τυπησομαι; while the firſt future is from the obſolete in [illegible].

The termination ην of the two aoriſts paſſive is borrowed from verbs in μι; and from this form, though obſolete, verbs in theſe tenſes are in reality derived. Thus ετυπην, which is erroneouſly ſuppoſed the ſecond aoriſt paſſive, is only the paſt of verbs in μι; as σπαρημι, (the obſolete of σπειρω,) is εσπαρην; τυπημι, ετυπην. What grammarians call the firſt aoriſt paſſive is from verbs in φθεω; as τυφθεω, τυφθημι, ετυφθην; λεχθεω, λεχθημι, ελεχθην. In the third plural σ is dropped—φανθησαν, φανθην, φανθεν. So in the active voice, τυπτοιεν for τυπτοιησαν; τιθειεν for τιθειησαν; ετυψαν for ετυψασαν; and ετυπτον for ετυπτοσαν. In the infancy of language, while words were yet ſcanty, the moſt natural way whereby a writer or ſpeaker might give an additional weight to his meaning, was to repeat ſuch terms as he wiſhed to render *emphatic*. The more ancient any language is, the more numerous appear the traces of ſuch repetition; and, next to the Hebrew, they form a remarkable feature in the Greek tongue. Thus, μαω, μαω, *I deſire, deſire*, blended into one word, become μιμαω, and means *I greatly deſire*; βαω, βαω, *I walk, walk*; βιβαω, *I ſtride*: and ſuch words are numerous in this tongue; from which we may draw the following inferences.

Firſt, that the augment is only the remains of a verb *doubled*, in order to augment the ſenſe. *Secondly*, this augment takes place in the preſent tenſe as well as in the imperfect; as ταινω, τιταινω; κληγω, κικληλω; θημι, τιθημι. *Thirdly*, that the augment of the imperfect, and of the aoriſts, is but a corruption, ſtill more remote of the reduplication; and that the dialect, which prefixes a conſonant to the vowel like the perfect, ſuch as πεπληγοντο, for επληγοντο is the moſt ancient uſage, and comes neareſt to the primitive ſimplicity of the language. *Fourthly*, the augment is applied to the firſt and ſecond futures; and the effect of it is to increaſe the ſignification of the verb; τυψω, τετυψω; κραξω, κεκραξομαι, *I will cry loudly*; καμω, κεκαμω, *I will greatly fatigue*. *Fifthly*, that the form called by grammarians *paulo poſt futurum*, is not a diſtinct tenſe, but the firſt future middle augmented: τισομαι, τετισομαι; τυψομαι, τετυψομαι. *Sixthly*, that the augment of the perfect comes neareſt to the original reduplication than that of any other tenſe, which is preſerved ſtill more diſtinctly in the augment of verbs beginning with vowels ολ-ωλα, οπ-ωπα, and the like.

The Ionians, we have obſerved, changed ν into α; and this analogy, perhaps, converted the imperfect form τετυπον, or τετυφον, into τετυπα, or τετυφα. The third perſon plural would be then τετυφασαν. Hence the Bœotians uſed τετυφαν. The Dorians write τετυφαντι, which, in the common tongue, is ſoftened into τετυφασι. The ſimple and natural way of forming the perfect was to give it the characteriſtic of the preſent which it always implies, as an action, though paſt, ſtill continuing in its effect; τυπτω, τετυπα; λεγω, λελογα. But from the facility by which letters of the ſame organs are changed for one another, τετυπα became τετυφα, and λελογα, or λελεγα, became λελεχα. Hence τετυπα, and λελογα, which are improperly called the perfect middle, ſeem to have been the original perfect active, accidentally corrupted. And as there is no foundation for the diſtinction of perfect active and perfect middle, in fact there is none in ſignification. When, from whatever cauſe, α in ſome verbs became the characteriſtic of the perfect, it prevailed in other verbs, which ſtill retained the characteriſtic of the preſent—πειθω, πεποιθα, πεπεικα. The diſtinction, therefore, of perfect active and perfect middle is a fiction of grammarians, founded on the interchange of ſimilar conſonants, or the blind impulſe of analogy.

Prepoſitions form the moſt difficult part of the Greek tongue, not only becauſe they, for the moſt part, govern different caſes, but becauſe each has a great variety of ſignifications. Yet the author of the Greek grammar, above mentioned, has laid down two obſervations, which tend greatly to ſimplify this branch of the Greek language. The primary meaning of a prepoſition, ſays he, is to be ſought in the root from whence it is derived, and the meaning ſo obtained, or one obviouſly connected with it, and flowing from it by analogy, it preſerves in all caſes whatever. A prepoſition combines with its own ſignification the meaning of the caſe in which the dependent noun is uſed; and it governs the genitive, the dative, or the accuſative, as the writer wiſhes to fix the attention of his readers on the *origin*, the *inſtrumentality*, or the *object* of the governed noun.

We cannot forbear tranſcribing one inſtance (which is the firſt that occurs) of his manner of explaining the prepoſitions—ὑπο (from the Hebrew אב, *ab, a ſtem* or *root*; and as the root is underneath, the plant or tree ſpringing from it, the primary ſenſe of ὑπο is) *under*, ὑπο ασπιδος, *under a ſhield*. Farther, the root of a tree is the *cauſe* of its growth; hence ὑπο denotes the cauſe or *agent* of the action ſpecified in connection with it. "And they were baptized *by him*, ὑπ' αυτου; he being the cauſe of their baptiſm." Finally, as a root ſhoots upwards, ſo as to appear above the ground, ὑπο is ſometimes to be rendered *from under*—ὑπο ζευγοῦ *from under the yoke*—απο, (from the ſame Hebrew origin with ὑπο; and as the root is the origin of a thing, it denotes *beginning, cauſe, motive*, and is rendered) *from*. As by the uſe of απο, the attention is directed backward to the beginning of motion, its governed noun is always in the genitive. "He was not able to ſee Jeſus, απο οχλου, *from the crowd*," *the crowd being the cauſe of his inability*. From ſignifying beginning, απο came to expreſs the exact point of time at which motion begins. "They went *from ſupper*, απο δειπνου, *i. e. immediately after ſupper*. It expreſſes alſo the *diſtance* to which a thing has advanced, in conſequence of moving, απο της γης, *far from the land*. The conſequence of diſtance in moſt caſes is *ſeparation*, or *privation*, απο των ὁπλων, *from their arms*, i. e. *without them*. Taken in this ſenſe, απο, abbreviated into α, as in Latin *ab*, becomes *a*, and compounded with nouns, adjectives, and verbs, imparts to them a contrary ſignification; πτολεμος, *war*, απτολεμος, *unwarlike*. On the contrary, the effect of diſtance in ſome caſes is *increaſe*, as a ſtream grows larger the farther it flows from its ſource, or as a tree becomes greater with its gradual expanſion from the root. For this reaſon απο abbreviated, ſometimes increaſes the ſignification of its compound.

The Greek ſurpaſſes almoſt all other languages in the number and variety of its terms; and the cauſes of its ſuperior copiouſneſs are, *firſt*, the many dialects which it comprehends, and which ſerved to divide by accidental corruption the ſame primitive into many words; *ſecondly*, the facility with which nouns combined with the perſonal pronouns in the formation of verbs, and the great variety of ways the ſame noun may be converted into verbs, ſo as to form diſtinct verbs, yet allied in ſenſe and ſound to each other; *thirdly*, the various ways in which verbs, adjectives, and participles have been changed into abſtract nouns; and *laſtly*, the great multitude of compound terms, formed by the union of verbs or adjectives with nouns, and of prepoſitions with verbs. The combination indeed of prepoſitions with ſimple verbs is the moſt fertile cauſe of the extent and comprehenſion of the language. The ſimple verb βαλλω, thus combined, has given birth to no leſs than *fifty-two* compound verbs. This ſingle inſtance ſufficiently ſhews the genius of the language, and proves that, however few its ſimple primitive words may have been, its derived and compound words are in a high degree voluminous and varied, yet connected by an obvious and uniform analogy, both in regard to the formation and the meaning of each term.

But this language is not leſs remarkable for the harmony of its ſtructure, than for the comprehenſion and variety of its terms. The perfection of language, as well as of muſic, depends on the melody of its ſounds; their meaſure or rhythm, their variety, and their ſuitableneſs to the ſubject, which they are meant to deſcribe or expreſs. The circumſtances of the Greeks in the earlieſt periods of their ſociety, rendered them peculiarly attentive to all theſe objects. They lived continually in crowds; all matters of conſequence were decided by the voice of the aſſembly, and, next to the force of his arms, every warrior felt himſelf indebted to the perſuaſive accents of his tongue. The perpetual neceſſity of employing the power of eloquence, during the infancy of their political ſtate, made them retain the original tones and cadences, by which men, as yet unpractiſed in the uſe of arbitrary ſigns, had made known their affections and their wants. Theſe tones and cadences, imitating the language of action, (the firſt and moſt natural language of ſavages,) poſſeſſed a degree of energy and of warmth which can never be attained by the mere artifice of articulate ſounds. By uniting them to theſe ſounds, the Greeks gave all the force of a natural to an arbitrary ſign. Muſic and action were incorporated in the ſubſtance of their ſpeech; and the deſcriptive power of words was extended to all thoſe objects which can be characterized by ſound and motion, or which the various modifications of thoſe qualities can ſuggeſt to the mind of man. Gillies' Hiſt. of Greece, vol. i. p. 238.

GREEK, *modern* or *vulgar*, is the language now ſpoken in Greece, and called Ρωμαικη γλωσσα, from Conſtantinople being called *Roma Nova*.

There have been few books written in this language, from the taking of Conſtantinople by the Turks; ſcarcely any thing but ſome catechiſms, and the like pieces, compoſed or tranſlated into the vulgar Greek, by the Latin miſſionaries.

The native Greeks are contented to ſpeak the language without cultivating it; the Turkiſh politics not allowing any of the ſubjects of their eſtates to apply themſelves to the arts and ſciences.

It is not eaſy to aſſign the preciſe difference between the *vulgar* and the *ancient* Greek: it conſiſts of the terminations of nouns, pronouns, verbs, and other parts of ſpeech, which make a difference between thoſe two languages much like that obſerved between ſome of the dialects of the Italian or Spaniſh: we inſtance in thoſe languages as being the moſt known; but we might have ſaid the ſame thing of the Hebrew, Sclavonic, &c. dialects. The *modern* Greek alſo curtails words, runs them into one another, and adds a ſort of enclitic particles to the end of them: it confounds the vowels η, ι, υ, and the diphthongs ει and οι, which they pronounce and often write only *iota*. They likewiſe often confound caſes, moods, tenſes, and particles. See Brerewood's Inquiry concerning the Diverſity of Languages, &c. chap. 2.

Beſides, the modern Greek has divers new words not in the ancient; particularly ſeveral participles which appear as expletives, and which are introduced to characterize certain tenſes of verbs, and other expreſſions, which would have had the ſame meaning without ſuch particles, had cuſtom diſpenſed with them; divers names of dignities and offices unknown to the ancient Greeks; and abundance of words borrowed from the vulgar tongues of the neighbouring nations.

Accordingly one may diſtinguiſh three ages of the Greek tongue: the firſt ends at the time when Conſtantinople became the capital of the Roman empire; not but there were ſeveral books, eſpecially of the fathers of the church, written with great purity after that time; but as religion, law, and policy both civil and military, began then to introduce new words into the language, it ſeems neceſſary to begin the ſecond age of the Greek tongue from that epocha, which laſted to the taking of Conſtantinople by the Turks, where the laſt age commences.

GREEN, in *Biography*, an organ-builder, on the model of Snetzler, whom he ſucceeded, and has left behind him monuments of his ſkill and ingenuity in many of our churches and manſions of the nobility and gentry.

To this modeſt and ingenious man, ever ready to adopt any hint tending to the perfection of his art, we are indebted for the improvement of the mechaniſm of the moſt noble and comprehenſive of all inſtruments, having eaſed the touch, voiced the pipes, and contrived a ſwell of the whole inſtrument, in a manner ſuperior to any of his predeceſſors. He died when ſcarcely arrived at the midway of the period of mortal life.

GREEN, MATTHEW, was born, probably in London, about the year 1696. He was educated among the diſſenters, and his learning extended to the knowledge of a little Latin. At this period, thoſe who diſſented from the eſtabliſhed church were rigid in their principles and gloomy in their manners. He appears to have been, on this account, diſguſted with thoſe who were the aſſociates of his youth, and to have completely abandoned the party. He ſpeculated freely on religious ſubjects, and at length adopted the ſyſtem of outward compliance with eſtabliſhed forms. At one time he appeared to be ready to join the quakers, but ſomething occurred which prevented him from making an outward profeſſion of their principles. His circumſtances were very narrow, but he was fortunate enough to obtain a place of ſome truſt in the Cuſtom houſe. He died at the age of forty-one, in the year 1735. His diſpoſition was remarkably mild, and his converſation abounded with wit. He was ſubject to low ſpirits: as a cure for this, he compoſed the work by which, as an author, he is principallly known, "The Spleen." This poem preſents a picture of his mind and manners, which implies a practical philoſophy of the ſober and rational Epicurean caſt. The other works of Mr. Green conſiſt of "The Grotto;" "Verſes on Barclay's Apology;" "The Seeker;" and ſome ſmaller pieces. "In manner and ſubject," ſays the critic, "they are ſome of the moſt original pieces in the language: they rank among the eaſy and familiar, but are replete with uncommon thoughts, new and ſtriking images of remote ideas by ſome unexpected ſimilitude, in which wit principally conſiſts. Few poems will bear more repeated peruſals; and with thoſe who can fully enter into them, they do not fail to become favourites." Gen. Biog.

GREEN, one of the original colours of the rays of light. Graſs and herbs, and even all vegetables in places expoſed to the open air, are green; and thoſe in ſubterraneous places, or places inacceſſible to the air, white and yellow. Thus when wheat or the like germinates under-ground it is white or yellow; and when it is in the open air, green; though this too is yellow before it be green.

GREENS, *Artificial*, are very rarely ſimple colours, but produced by mixture of yellow and blue.

Two powders, the one blue, and the other yellow, well mixed, appear perfectly green; though, when viewed with a microſcope, we obſerve a chequer of blue and yellow.

The tincture of red roſes with oil of tartar per deliquium, or with ſpirit of ſal ammoniac, produces green. The tincture of many red flowers is changed into green by an alkali. The tincture of red roſes, and the yellow tincture of crocus, or the blue tincture of cyanus, and the white ſpirit of ſal ammoniac, produce green. The ſolution of verdigris becomes colourleſs by the affuſion of the ſpirit of nitre, and by the affuſion of the oil of tartar it becomes green again.

As no vegetable has yet been diſcovered, which is capable of giving to cloth of any kind a permanent green colour, the dye for this purpoſe is a compound colour, formed in dye-vats either by putting a yellow on a blue ground, or a blue on the yellow ground, or by mixing the blue and yellow materials, and dyeing with them as with a ſimple colour. The common and moſt permanent green is given to woollen cloth in the following manner. The cloth, being firſt dyed blue in the indigo vat (ſee INDIGO), is then well ſcoured, and afterwards dyed in a bath of weld or any other yellow dye with alum and tartar, as in the mode of dyeing of ſimple yellows, except that the yellow materials are uſed in greater quantity than the yellow alone of equal body would require. Very deep greens are made to acquire a ſlight brown or kind of burniſh by adding to the bath ſmall quantities of logwood and ſulphat of iron. As for ſilks, they are firſt ſtrongly alumed, then dyed yellow with weld, and afterwards finiſhed in the indigo vat. Silk, cotton, and linen are dyed green in the ſame general mode, but with conſiderable variations in the different proceſſes. The moſt beautiful green hitherto known, and which perfectly well reſiſts the action of light and air, is given by the combination of Pruſſian blue and yellow, but this colour is deſtroyed by ſoap and alkalies. To cotton this colour is given, by firſt dyeing it olive with weld, or any other yellow dye, and a compound mordant of alum and iron, and then raiſing the green by pruſſiat of potaſh. (See PRUSSIAN *blue*.) Berthollet obſerves, that in the proceſs for this purpoſe there ſeems to be a mutual diſtribution of the mordants and colours, the Pruſſian colour taking the iron and becoming blue, whilſt the alum and weld remaining in the olive form a faſt yellow, and unite with the blue into a fine green. The only ſimple green in common uſe is that of the carbonated oxyd of copper precipitated from verdigris by an alkali. A ſolution of verdigris is made in vinegar, and a few hours before dyeing a ſolution of as much pearlaſh as verdigris is added to it, the mixture is heated, and the cotton, previouſly alumed, is paſſed through this bath. The colour then given is a ſoft apple-green. Aikin's Dict.

The dyers make divers ſhades, or caſts of green, as *light* green, *yellow* green, *graſs* green, *laurel* green, *ſea* green, *dark* green, *parrot* green, and *celadon* green.

GREEN, *Brunſwick*, is a pigment uſed by ſome of the German artiſts, which they prepare by adding to the ſaturated ſolution of one part of muriated ammonia in cold water, three parts of copper clippings; and by covering the glaſs veſſel that contains it with gauſe ſo as to keep out the duſt, and placing it in a warm ſituation, ſo that the moiſture may evaporate, which purpoſe will be effected in a few days. The muriat of ammonia ſoon begins to be decompoſed by the copper, which is corroded and converted into a green oxyd. When the whole is evaporated to dryneſs, let it be digeſted in two or three ſucceſſive portions of ſpirit of wine, as long as any green oxyd is taken up; then add the ſolutions together and expel the liquor by a gentle heat, the reſidue is a pure dark green ſub-muriat of copper, known in the ſhops by the name of refined Brunſwick green.

GREEN, *Mountain*, or *Hungary green*, is a ſort of greeniſh powder found in little grains, like ſand, among the mountains of Kernauſent in Hungary, and thoſe of Moldavia. Though ſome hold, that this mountain green is factitious, and the ſame with that the ancients called *flos æris*, prepared by caſting water, or rather wine, on copper red-hot from the furnace, and catching the fumes thereof on copper plates laid over for that purpoſe: or by diſſolving copper-plates in wine, much as in making verdigris. The painters make uſe of this colour for *graſs* green. It is ſometimes counterfeited by grinding verdigris with ceruſe.

GREEN, *Calcined*, and *diſtilled green*. See VERDIGRIS.

GREEN, *Pruſſian*. See the proceſs for making PRUSSIAN *blue*.

GREEN, *Sap*. See *colours from* FRUITS, BUCKTHORN, and SAP-*green*.

GREEN, *Saxon*, an extremely beautiful green colour, ſo called becauſe the blue part is given by the Saxon blue or ſulphat of indigo; the proceſs of dyeing which is this; the cloth or ſilk is firſt to be dyed a Saxon blue, in the following manner. Having ground nine parts of indigo with twenty of red arſenic into a fine powder, add forty-eight parts of ſtrong ſpirit of vitriol; which mixture ſwells, grows hot, and emits a ſulphureous ſmell. After ſtanding in a moderate warmth of twenty-four hours, pour off the liquid part, which will be of an extremely deep blue. A ſmall quantity of this liquor, dropt into hot water, inſtantly ſpreads, tinges it of a fine light blue, and fits it for dyeing the prepared wool, cloth, or ſilk ; and by increaſing or diminiſhing the proportion of the blue compoſition, the colour may be rendered deeper or lighter. This, Dr. Lewis ſays, is the method uſed for preparing the blue compoſition by the dyers of Norwich, who purchaſed this ſecret from Saxony.

The cloth or ſilk, thus dyed blue, is next alumed, and then dipped in the yellow decoction of weld or fuſtic, and the deſired colour will be obtained.

Fuſtic is commonly preferred as the yellow material, becauſe it is leſs liable to be altered by the adhering acid of the ſulphat of indigo than weld or the other yellows. To correct this effect of the acid, and enable quercitron to equal the fuſtic in this reſpect, (whilſt its natural colour much excels it,) Dr. Bancroft adviſes, after the cloth has received the blue, to mix chalk with the alum mordant, in order to neutralize the adhering acid, before the yellow is given.

Or the ſubject may be dyed green at one operation, by boiling it for a little time in a mixture of the blue and yellow liquors. For this purpoſe the cloth is firſt alumed and well rinſed ; and the cloth is then dyed in a ſtrong decoction of fuſtic, to which, when cooled to a blood heat, is added ſulphat of indigo. Dr. Bancroft recommends for dyeing a beautiful Saxon green, the following expeditious proceſs, by uſing the compound alum and tin mordant ; put into the boiler ſix or eight pounds of quercitron bark to every one hundred pounds of cloth ; boil with a ſufficient quantity of water ; then add ſix pounds of the murio-ſulphat of tin, (in preference to the nitro-muriat,) and four pounds of alum : when theſe have boiled five or ſix minutes, lower the heat with cold water to blood-warm, after which, add as much ſulphat of indigo as may be thought neceſſary for the intended depth of colour, and then dye the cloth in this bath with proper care. Aikin's Dict.

By combining any blue and yellow dyes, in different proportions, all the ſhades of green may be produced, from the blueiſh green of the cabbage-leaf to the greeniſh-yellow of the olive.

Green, in *Agriculture*, a term provincially ſignifying graſs-land, or ſuch as is in the ſtate of turf.

Green, in *Geography*, a county of America, in New York, taken from Ulſter and Albany counties, bounded on the N. by Albany and Schoharie, E. by the river Hudſon, S. by the county of Ulſter, and W. by the county of Delaware ; 30 miles in length from E. to W., and from 12 to 20 in breadth. The number of its inhabitants is 15,870, and its chief town is Kaatſkill.—Alſo, a county of Pennſylvania, bounded N. by Waſhington, S. and W. by Virginia, E. by Monongahela river ; 33 miles long, and 18 broad. The number of its inhabitants is 8605.—Alſo, a county of Kentucky, extending from Ohio river on the N., to Teneſſee ſtate on the S., and bordering W. on the Miſſiſſippi river, and E. upon Hardin and Jefferſon counties. The number of its inhabitants is 6025, of whom 816 are ſlaves.—Alſo, a county of N. Carolina, in the diſtrict of Newbern, containing 4218 inhabitants, of whom 1496 are ſlaves.—Alſo, a poſt-town in Kennebeck county, and ſtate of Maine, ſituated on the E. ſide of Androſcoggin river, 164 miles N.E. from Boſton ; containing 933 inhabitants.—Alſo, a poſt-town in Franklin county, Pennſylvania, ſituated near the Conegocheague creek ; 156 miles W. by S. from Philadelphia ; containing about 80 houſes, 2 German churches, and a Preſbyterian church, and 884 inhabitants.—Alſo, a townſhip in Franklin county, and alſo a townſhip in Waſhington county, in the ſame ſtate.—Alſo, a navigable river of Kentucky, which riſes in Mercer county, has a gentle current, generally in a W. direction, and is navigable nearly 150 miles : at its confluence with the Ohio it is upwards of 200 yards wide.—Alſo, a ſmall river which riſes in the town of Marlborough, in Vermont, and falls into Connecticut river, above Deerfield, in Maſſachuſetts.—Alſo, a river of New Brunſwick, which runs into the St. John. N. lat. 47 20'. W. long. 67 58'.—Alſo, a river of Canada, which runs into the river St. Lawrence, 106 miles below Quebec.

Green *Bank*, one of the banks near the iſland of Newfoundland ; 129 miles long, and 48 wide. N. lat. 45° 30'. to 46 50'. W. long. 53° 30' to 53° 50.'

Green *Bay*, a bay on the W. ſide of lake Michigan, about 90 miles long, and 15, 20, or 30 broad in different parts, lying nearly from N.E. to S.W. At its entrance is a ſtring of iſlands extending N. to S., called the "Grand Traverſe ;" theſe are about 30 miles in length, and ſerve to facilitate the paſſage of canoes, as they afford them a ſhelter from the winds. The communication between lake Michigan and the Green bay is ſufficiently deep for a veſſel of 60 tons, with a proportionable breadth ; the land adjoining to the bottom of the bay is very fertile, the country generally level, and the views of it agreeable and extenſive. The inhabitants of its coaſts call this bay the Menomie bay. N. lat. 45°. W. long. 87° 58'.—Alſo, a bay on the E. coaſt of the iſland of Antigua, S. from Green iſland.

Green *Briar*, a large and fertile county of Virginia, ſurrounded by Bath, Randolph, Harriſon, Kanhaway, Botetourt, and Montgomery counties : about one hundred miles long and 45 broad : containing 3894 free inhabitants, and 271 ſlaves. The chief town is Lewiſburg ; 103 miles W. of Staunton.—Alſo, a river of Virginia, which purſuing a S.W. courſe, runs into the eaſtern ſide of the great Kanhaway. N. lat. 37° 57'. W. long. 80° 58'.

Green *Bug*, in *Agriculture*, the name of a ſmall inſect, which is often found deſtructive to different plants in both fields and gardens. It alſo frequently proves deſtructive to hop crops. It is very difficult to deſtroy it in many caſes.

Green *Cheeſe*, in *Rural Economy*, the name of that ſort of cheeſe which is prepared with ſome kind of green vegetable juice, as that of ſage and other ſimilar plants.

Green *Copperas*, See Copperas, and *Sulphat of* Iron.

Green *Creek*, in *Geography*, a river of Pennſylvania, which runs into the Suſquehanna. N. lat. 40° 58'. W. long. 76 30'.

Green *Crop*, in *Agriculture*, that ſort which is formed of ſome kind of green vegetable ; ſuch as that of ſome ſort of artificial graſs, the turnip, cabbage, tare, rape, &c. which are ſo termed in contradiſtinction to thoſe of the grain deſcription. The introduction of crops of this nature between thoſe of the grain kind, has conſtituted one of the moſt important improvements in modern agriculture. By this means, land has not only been prevented from being exhauſted and worn out, but brought into the moſt proper condition for the growth of grain, without undergoing the injurious proceſs of naked or ſummer fallowing. It has likewiſe had the effect of greatly increaſing the number, and improving the quantity of all ſorts of live ſtock, in conſequence of their having more abundant ſupplies of food, and theſe at the ſame time of better qualities. There can therefore be no doubt of the great advantage of theſe crops, which ſhould of courſe be grown as extenſively as poſſible by the farmer, as by them he may be enabled to ſupport much larger ſtocks of cattle and ſheep than could otherwiſe be the caſe, and at the ſame time raiſe much larger quantities of good manure. See Manure. Beſides this, great advantage might, in different inſtances of cattle-farms of the breeding kind, be derived from the more extenſive cultivation of ſuch green crops as the winter ſupport of the ſtock.

And crops of this nature have likewiſe been found of extenſive utility in the feeding of milch-cows in winter dairying, as is fully ſhewn in the various trials made by J. C. Curwen, eſq. in a northern diſtrict of the kingdom, in the view of ſupplying the poor of a large town with milk. The value of which crops in this ſort of application, on the ſuppoſition of their being ſold to the cow-keeper, and the expences of their cultivation, are ſtated in the following manner.

Green Crops.

				£.	*s.*	*d.*
Twenty-two acres of green crop, at 10*l.* *per* acre - - -				220	0	0
Expences of raiſing and cleaning.						
Four acres of cabbages, at 12*l.* *per* acre	48	0	0			
Two acres of Swediſh turnips, at 5*l.* *per* acre	10	0	0			
Six acres of common red turnips, at 4*l.* *per* acre	24	0	0			
One acre of Kahlrabi -	5	0	0			
Nine acres of rape or cole, at 3*l.* 10*s.* *per* acre	31	10	0			
				118	10	0
Gain on crops £.				101	10	0

It is conſidered that the improvement of the land, and the value of the ſucceeding crops, are fully adequate to the rent and taxes.

This ſtatement ſhews in the moſt clear point of view the vaſt benefit of this kind of crops even in this ſort of application, and that they ſhould not be diſregarded by thoſe engaged in the buſineſs of huſbandry. But in ſome other modes of application they will be found far more important and beneficial.

By ſome they have alſo been conſidered as of great utility when turned into the ſoil by way of a manure, though others are wholly of a different opinion; probably in conſequence of the trials having been made in very oppoſite deſcriptions of ſoils, and under very different circumſtances of them. It is extremely probable, likewiſe, that the advantage of this practice will be much greater where the crops are turned in during the ſummer months than in other caſes, in conſequence of their running more quickly into the putrefactive ſtate. It has been adviſed, that whatever may be the nature of the crops, they ſhould be ploughed under by means of a ſkim-coulter plough, as conſtituting the only means of turning them in, in ſo complete a manner as wholly to conceal them. And that, in caſe of ſowing the land with broad caſt turnips, the work ſhould be performed at leaſt three weeks before the ſeed is put into the ſoil, and that it ſhould be afterwards only very ſlightly harrowed in. See *Turning in Green* CROPS.

GREEN *Earth*, in *Mineralogy*, *Baldogee*, Sauſſ.; *Chlorite baldogée*, Brong.; *Argilla veronenſis*, Wern.; *Grünerde*, Wern.; *Talc chlorite zographique*, Haüy; *Verde di Verona*, *Verde di Brentonico*, Ital.; Veroneſe earth, an earthy ſubſtance belonging to the argillaceous genus. Its colour is indicated by its name, but there are ſeveral ſhades of it, the principal of which are verdigris, and celadon green, paſſing ſometimes into leek and mountain green, frequently with an admixture of grey; it has alſo been obſerved of a more or leſs pure olive green.

It occurs maſſive and diſſeminated, in rounded and angular fragments, and in globular concretions; likewiſe in grains mixed with ſand, and as coating on agate balls, in the hollows of amygdaloid, (toad-ſtone,) &c. Internally it is dull, but on the rifts a fat-like luſtre is ſometimes obſervable.

Fracture fine-earthy, or more or leſs flat conchoidal, approaching to ſlaty. Diviſible into indeterminately angular, blunt-edged, opaque fragments.

It feels rather greaſy, is always more or leſs ſoft, mild, and eaſily frangible; ſtreak rather ſhining; adheſion to the tongue inconſiderable. Specific gravity about $2\frac{1}{2}$.

The chemical characters of green-earth, derived from Klaproth's analyſis of three varieties, *viz.* thoſe from Monte Baldo, in the Veroneſe, from Cyprus, and from Eaſt Pruſſia, are the following:

The green-earth from Monte Baldo, when heated to redneſs, loſes ſix per cent. of its weight, while its hardneſs is conſiderably increaſed. The fragments thus ſubjected to the fire become externally of a yellowiſh-brown colour, internally greyiſh-black and gliſtening. That of Cyprus, after ignition, loſes eight parts of its weight; and its colour is converted into dirty browniſh-yellow. Expoſed to the fire of the porcelain furnace in the charcoal crucible, it fuſes to a ſomewhat porous greeniſh glaſs, externally of a dirty-green colour, internally of that of emerald; in the clay crucible it is converted into a greeniſh-grey ſlag. The green-earth of New Eaſt Pruſſia, when freed from the admixed ſand by elutrition, and ignited, changes its green colour into light leather-brown; the conglomerated particles are converted into a hard maſs, and thus loſe nine per cent. of their weight. The acids do not act upon green-earth, and they leave its colour unaltered.

The reſults of the analyſes of the above three varieties were:

Green-earth of Monte Baldo, in the Veroneſe.		Green-earth of Cyprus.	
Silica - -	53		51.50
Oxyd of iron -	28		20.50
Magneſia -	2		1.50
Kali - -	10		18.
Water - -	6		8.

Water - - - - - -	9.
Loſs - - - - - -	50
ibid.	100

The Pruſſian green-earth, by thus differing from the two others, particularly with regard to the alumina as a conſtituent part, appears to approach the nature of chlorite.

Green-earth occurs principally in amygdaloid, alſo as incruſtation on the nodules of zeolite, &c. contained in the vacuities; ſometimes as coating the ſides of theſe vacuities, which are often partly filled with the earth. It is alſo, though leſs frequently, found in porphyry and baſalt, as nodules in the newer ſandſtone, and even in the rocks belonging to the new fletz-trap-formation, ſuch as at Aſchau in Bohemia, where calcareous tuff is ſeen alternating with narrow layers of a conglomerate, made up of grains of calcareous ſpar, and blunt-edged fragments of the tuff to which the green earth ſerves as the cementing ſubſtance. But in the ſame place green-earth forms a fletz-layer of about a foot in thickneſs, whoſe baſe conſiſts of wacke-like clay and calcareous tuff; the roof of indurated marle. The green-earth of New Eaſt Pruſſia, conſiſting of earthy particles mixed with a coarſe ſand, forms a conſiderable bed in the neighbourhood of the river Memel, between Loſſoſſna and Salloweye.

Among the *localities*, beſides thoſe of Monte Baldo in the Veroneſe, Cyprus, Pruſſia, and Bohemia, already pointed out, the following may be mentioned: Altenburg and Planitz, in Saxony; Oberſtein, in the Palatinate; Kovaeſi, in Hungary; Pontaudemer, in Normandy; Scotland, Iceland, the Ferroe-iſlands, and wherever true amygdaloid occurs.

This earth is *uſed* as a pigment, particularly for water-colour painting; and, being very durable, and not too expenſive, alſo for houſe painting, &c.

The green-earth of Cyprus, according to Mariti, is ſold at 4½ piaſters for a meaſure of 100 cakes. It is carried from the pit in large baſkets made of the palm-tree; three of theſe baſkets generally contain the above mentioned quantity. A great deal was exported to Holland; often by way of ballaſt.

That of Bohemia, above mentioned, is ſold, according as its colour is deeper and its grain finer, from two to four florins the cwt. Part of it is alſo burnt there in ſmall kilns, and ſold as a red pigment.

By the Italians green earth is called Verde di *Brentonico*, from the vicinity of Monte Bolca to a place of that name.

Green *Fallow*, in *Agriculture*, a term often applied to ſuch arable land as is rendered clean and free from weeds, by means of green crops, without having recourſe to the proceſs of naked or ſummer fallowing. This conſtitutes one of the numerous improvements in modern huſbandry. See Fallowing *of Land*.

Green *Finch*, in *Ornithology*. See Loxia *Chloris*. See alſo Tanagra *Gyrola*, and Fringilla *butyracea*.

Green *Fiſh*. See *Cod*-Fishery.

Green *Food*, in *Agriculture*, that ſort of food which is employed in its green or ſucculent condition, in the feeding, foddering, and ſupporting of various kinds of live ſtock. This is a ſort of food that has, within theſe late years, been much more extenſively employed than was formerly the caſe; yet its advantages are probably in general not ſo fully underſtood as they ought to be. Its importance and utility will, however, ſoon appear by the making of a few experiments in a proper manner.

Green *Glaſs*. See Glass.

Green *Hew*, or *green-hue*, in our *Old Writers*, the ſame with *vert* in foreſts, &c.

Green *Hides*, are thoſe not yet tanned, or dreſſed, but ſuch as are taken off from the carcaſes. See Hide and Currying.

Green *Iron Earth*. See Iron.

Green *Iſland*, in *Geography*, a ſmall iſland among the Philippines, near the S. coaſt of the iſland of St. Luçon. N. lat. 13° 30′. E. long. 121° 2′.—Alſo, a ſmall iſland in the Eaſt Indian ſea. S. lat. 6° 5′. E. long. 123° 30′. Alſo, one of the ſmaller Bahama iſlands. N. lat. 21° 38′. W. long. 57°.—Alſo, one of the leſſer Virgin iſlands, called likewiſe "Serpent iſland," ſituated near the E. end of Porto Rico.—Alſo, a low woody iſland near the N. E. coaſt of New Holland; 12 miles E. N. E. of Cape Grafton. S. lat. 16° 48′. W. long. 214° 5′.—Alſo, an iſland in Hudſon's bay. N. lat. 61° 2′. W. long. 72° 40′.—Alſo, an iſland in the Atlantic, near the coaſt of Main. N. lat. 44° 41′. W. long. 67° 23′.—Alſo, a ſmall iſland near the E. coaſt of Antigua. N. lat 17° 13′. W. long. 61° 21′.—Alſo, a ſmall iſland in the Weſt Indies, about a mile N.E. from the iſland of St. Thomas.

Green *Iſlands*, a cluſter of ſmall iſlands in the Pacific ocean, diſcovered by Schouten and Le Maire. N. lat. 4° 53′. E. long. 154° 50′.—Alſo, a range of ſmall iſlands in that part of the Eaſt Indian ſea, called the "ſea of Mindero," near the E. coaſt of Palawan. N. lat. 9° 33′. E. long. 119° 6′.—Alſo, a group of low iſlands in Prince William's ſound, ſituated within the S.W. channel, between Montagu's iſland and Knight's iſland. Capt. Cook, in his third voyage, 1778, obſerved that they were entirely free from ſnow, and covered with wood and verdure, and therefore called them by this name. The channel between Montagu iſland and the Green iſlands is between two and three leagues broad, and from 34 to 17 fathoms deep.

Green *Iſland Harbour*, a bay on the W. coaſt of the iſland of Jamaica. N. lat. 18° 24′. W. long. 78° 17′.

Green *Key*, or Puerco, a ſmall iſland among the Bahamas. N. lat. 23° 56′. W. long. 77° 50′.

Green *Lead Ore*. See Lead.

Green *Mountains*, in *Geography*, a range of mountains in America, extending N. N. E. to S. S. W. and dividing the waters which run eaſterly into Connecticut river from thoſe which fall weſterly into lake Champlain, lake George, and Hudſon's river. The aſcent from the eaſt to the top of the Green mountain in Vermont is much more eaſy than that from the weſt, till you get to Onion river, where the mountain terminates. The vegetables that naturally grow on this mountain are hemlock, pine, ſpruce, and other evergreens, which always exhibit a green appearance; and hence its name. The chain of mountains extends through Maſſachuſetts and Connecticut, and terminates in New Haven. Kellington peak, the higheſt of theſe mountains, is about 3454 feet above the level of the ocean. Morſe.

Green *Point*, a cape on the W. coaſt of Africa. S. lat. 11° 53′.—Alſo, a cape on the coaſt of Weſt Florida, in Penſacola bay. N. lat. 30° 31′. W. long. 87° 4′.

Green *Sauce*, in *Agriculture*, a term ſometimes provincially applied to the common ſorrel.

Green *Scouring*, a diſeaſe to which ſheep, calves, and cattle are frequently expoſed, and which is with difficulty removed. See Scour.

Green-*Shank*, in *Ornithology*, the Scolopax *glottis* of Linnæus; which ſee.

Green *Sickneſs*. See Chlorosis.

Green *Side*, in *Agriculture*, a term often provincially applied to graſs-land, turf, or ſward.

Green *Silver*, the name of an ancient cuſtom within the manor of Writtle, in the county of Eſſex; which is, that every tenant, whoſe fore-door opens to Greenbury, ſhall pay a half-penny yearly to the lord, by the name of *green ſilver*. Blount.

Green *Sod*, in *Agriculture*, a term provincially applied to graſs-ground, turf, or ſward.

Green-*Stone*, in *Mineralogy*, according to the more general acceptation of the word, is a rock compoſed of hornblende and feldſpar, and belonging to what is termed by Werner the trap formation. (See Trap.) Mica and quartz are likewiſe ſeen to conſtitute ingredients of this rock, but they are not conſidered as eſſentially belonging to it. The *Grœnſten* of Cronſted is, upon the whole, the ſame as our green-ſtone; but in ſome caſes too great latitude has been given to that name.

This rock, with a view to the periods of its formation, is divided into primitive, tranſition, and fletz green-ſtone.

The *primitive* green-ſtone is generally diſtinguiſhable from the others by its highly cryſtalline ſtructure. The hornblende, in which a tendency to cryſtallization is almoſt always obſervable, generally conſtitutes the predominant ingredient; but ſometimes this is only apparently ſo, the feldſpar being not ſeldom ſtained by it in ſuch a manner, that it bears the greateſt reſemblance to ſmall laminæ of hornblende. In this caſe the blow-pipe diſcovers the illuſion by melting the hornblende; when the feldſpar recovers its uſual whitiſh colour, and is converted into a white glaſs.

Werner ſubdivides primitive green-ſtone into four varieties: 1. *Common green-ſtone,* in which the two ingredients, mixed in different proportions, form a granular maſs. 2. *Porphyritic green-ſtone,* being the common variety, including large cryſtals of feldſpar. 3. *Green-ſtone porphyry,* in which "the granular baſis, which is with difficulty diſtinguiſhable, includes cryſtals of feldſpar:" and 4. *Green porphyry,* in which "the granular nature of the baſis is no longer viſible to the naked eye; it appears uniform and ſimple; has a blackiſh green or piſtachio green colour, and includes cryſtals of compact feldſpar." (Jameſon.) To theſe are to be referred the porſido nero, and porſido verde antico of Italian antiquaries, of which we ſhall ſay more hereafter. The third and fourth of theſe varieties might, we think, be ſafely united; at leaſt the definition given of them does not indicate any difference, except in the ſhade of green.

This old green-ſtone appears ſometimes ſtratified. Gneiſs is the rock in which the different varieties firſt appear; the next rock in which they occur is mica-ſlate, but the beds of green-ſtone in either of them are ſcanty and inconſiderable; they are obſerved more numerous and of greater extent in clay ſlate in Scotland. According to Mr. Jameſon, the clay-ſlate and mica-ſlate, that form a great portion of the country extending from Loch Lomond, by Callander, Comrie, and Dunkeld, contain numerous beds of green-ſtone; and there, we are informed by this geognoſian, as in all other countries, the clay ſlate contains more numerous and larger beds than the mica ſlate.

There is a vaſt number of varieties of primitive green-ſtone in Bohemia; thus it is found in the Saatz diſtrict of that country, where it reſts chiefly on gneiſs. It occurs there alſo with quartz as a conſtituent part. The varieties mentioned by Reuſs, as being found there within a narrow compaſs, are, 1. A ſmall grained mixture of velvet black hornblende, which exhibits a tendency to a priſmatic cryſtalline form, with yellowiſh white feldſpar, and greyiſh-white and ſmoke grey quartz. The hornblende is the predominant part; the quartz is here and there entirely wanting; the mixture pretty uniformly granular. 2. A variety in which the hornblende is ſeen in groups, diſtinct from thoſe of the feldſpar and quartz; ſo that the whole forms an aſſemblage of black and yellowiſh-white ſpots. 3. A variety in which the hornblende is ſo prevalent, that feldſpar and quartz can with difficulty be diſtinguiſhed by the magnifying glaſs, which diſcovers theſe ingredients collected into ſmall ſpots and ſtripes; it contains alſo here and there ſome ſcales of mica. 4. Var. in which the hornblende is ſeen partly maſſive, in ſpots, ſtripes uniformly blended with the feldſpar and quartz; partly in ſmall circular cryſtals that are divergingly aggregated, or croſs each other in all directions; feldſpar tile and browniſh-red; quartz only here and there in ſmoke grey grains. 5. Var. in which the hornblende ſhows a ſtrong tendency to cryſtallization, and is much accumulated in ſome places; though, generally ſpeaking, its proportion to the mixture of yellowiſh-white and reddiſh-grey feldſpar and greyiſh-white quartz, is but ſmall: it contains larger and more numerous ſcales of ſilvery and yellowiſh-white mica. 6. Var. in which the texture becomes more thick-flaky; the ſmoke-grey quartz becomes predominant, the yellowiſh-white feldſpar diſappears almoſt entirely, and the hornblende is only thickly diſſeminated. 7. Var. in which the yellowiſh-white and reddiſh-grey feldſpar predominates over the hornblende, which is ſeen partly maſſive and in fine granular concretions, partly in inſulated and diſperſed minute ſix-ſided priſms, imbedded in the feldſpar; while the quartz is entirely wanting. It is remarkable that in this diſtrict the primitive green-ſtone is ſeen, by ſlow gradation, to paſs over into perfect gneiſs. The more it approaches the latter, the more the granular texture becomes indiſtinct; the rock adopts a thick ſlaty texture, the hornblende is ſeen more and more to diminiſh, while the mica increaſes both in quantity and ſize, until perfect gneiſs ſtands confeſſed as the conſtituent rock.

This rock is common alſo in many other parts of Europe; but the accounts we poſſeſs of the green-ſtone of ſeveral countries is too imperfect to enable us to determine how much of it may be conſidered as primitive.

The *tranſition green-ſtone* is not eaſily diſcriminated in hand-ſpecimens. It is characterized by Mr. Jameſon as being "a fine granular mixture of hornblende and feldſpar; and ſometimes the mixture is ſo intimate, that the conſtituent parts are not to be diſtinguiſhed. Quartz ſometimes traverſes it in the form of veins, or is diſſeminated through it; a character which diſtinguiſhes it from fletz green-ſtone, which rarely contains quartz. Sometimes it occurs in globular diſtinct concretions, and theſe again conſiſt of curved lamellar concretions, forming the globular rock (kugelfels) of Voigtland. Sometimes it is penetrated with reddiſh brown oxyd of iron, which, combined with the dark-brown hornblende, gives the rock a liver-brown colour; hence it is denominated in Voigtland, where it occurs, leber-fels, or liver rock. Beds of it occur in the upper part of Dumfriesſhire, in the Hartz, Bohemia, &c."

Fletz-green-ſtone. Prof. Jameſon, in his "Mineralogical Deſcription of Dumfriesſhire," has given a ſhort account of the occurrence of green-ſtone in the independent coal-formation; and Mr. Flürl has diſcovered beds of amygdaloid in the firſt or oldeſt fletz-lime-ſtone; whence the former author conſiders himſelf entitled to introduce what he terms the *fletz-trap,* which is diſtinct from the ſtill newer formation called the *neweſt fletz-trap* by Werner. In the independent coal formation it occurs in beds from one foot to many fathoms in thickneſs; it contains imbedded olivine and augite, and is traverſed by numerous veins of calc-ſpar; it often alſo contains druſy cavities, which are lined with calc-ſpar, quartz, barytes, cubicite and prehnite; and the cavities are ſometimes filled with water.

The green-ſtone of Werner's *neweſt fletz-trap formation* is, upon the whole, diſtinguiſhable from the older formation, by its ſtructure being of a leſs cryſtalline appearance, and by its diſtinct concretions approaching more to the coarſe granular. "Its colour uſually inclines more or leſs to green. Certain varieties are reddiſh, and theſe are denominated ſienitic green-ſtone. When freſh and rather large granular, it uſually exhibits a ſimple ſtructure; when, on the contrary, it is diſintegrated, and ſmaller granular, it occurs in globular, and theſe again in curved lamellar diſtinct concretions. Certain varieties approach to wacke, and theſe are uſually veſicular, and form a kind of amygdaloid. It is ſometimes very diſtinctly ſtratified, and frequently occurs in veins." Jameſon.

The *uſes* to which the common green-ſtone is applied are not manifold. As it frequently contains a conſiderable portion of iron, and is ſufficiently fuſible, it ſerves for a flux in the iron work in Smoland. Of the porphyritic varieties of the primitive green-ſtone uſed for ornament, the following deſerve to be mentioned:

Antique black porphyries (porfido nero antico). There are two or three varieties differing, with regard to the intenſity of the colour, from greeniſh-black to velvet-black; and likewiſe with regard to the ſize of the whitiſh feldſpar-cryſtals: in one of them the cryſtals are very ſmall, and this is more frequently ſeen among the remains of antiquity than the other.

Mr. Graffenauer, in his mineralogy of Alſace, mentions a black porvhyry as occurring at Framont; and alſo as rounded blocks in the river Ill.

In the black *Corſican* porphyry, the feldſpar-cryſtals have a ſlight tint of green, like thoſe of the antique green porphyry. Ferber makes mention of a *Sardinian* black porphyry, and Sauſſure of one found in the neighbourhood of *Geneva*, which, beſides ſmall priſmatic cryſtals of feldſpar, includes rounded grains of tranſparent colourleſs quartz. The latter addition is likewiſe obſerved in a variety of a blackiſh *Siberian* porphyry, which is ſometimes wrought for ornamental purpoſes.

Antique green porphyry (porfido verde antico). This is the *ophites* of the ancients; a name derived from ſome ſuppoſed reſemblance of this rock, when poliſhed, to the ſkin of a ſerpent; whence, in modern times, antiquaries have referred the porphyry in queſtion to the magneſian ſtone called ſerpentine, a mixture of which, with primitive limeſtone, conſtitutes the rock called *verde antico.* When once conſidered as the ſame with the real ſerpentine, the name *verde antico,* of courſe, alſo was equally applied to the green porphyry; a circumſtance which has been productive of great confuſion. There are now but few monuments of ancient art executed in this porphyry to be met with.

There are ſome varieties of green porphyry, much reſembling the antique, ſtill found in ſeveral parts of Europe. There is a quarry of it on Monte Viſo, in Piedmont; which, beſides the feldſpar, contains reddiſh grains, ſuppoſed to be garnets.

The *green Corſican porphyry,* found in the diſtrict of Niotto, in Corſica, has a deep bottle-green baſe, and fine white feldſpar cryſtals; another, which contains ſome dark red garnets, occurs in the diſtrict of Golo in the ſame iſland.

Sauſſure deſcribes the *green porphyry of Geneva,* reſembling the black porphyry above-mentioned, in the figure and colour of the feldſpar and quartz, but differing in its baſe, which is light green and, in fragments, tranſlucid at the edges. Both this and the black take an excellent poliſh.

The *green porphyry of the Voſges* has a dark green baſe, and contains numerous middle-ſized feldſpar-cryſtals of a pale green colour. It is found at La Chevetrey, on the heights of Freſle en Comté, and made uſe of for ornamental purpoſes. In another variety, found not far from this quarry, the feldſpar-cryſtals are ſo preſſed againſt each other, that they are ill-formed, and conceal almoſt the whole of the baſe. They are manufactured into ſlabs for tables, chimney-pieces, &c. and ſometimes paſs by the improper name of green granite.

There is abundance of the green porphyry in the Pyrenees, where it is known by the old appellation of *ophite.*

Green-*ſtone ſlate,* a compound rock, which may be conſidered as a variety of the preceding, from which it differs in having a diſtinct ſlaty ſtructure; the feldſpar, moreover, being generally more abundant than the hornblende. It ranks with the primitive trap, but, not occurring in rocks older than clay-ſlate, is conſidered as the neweſt of the firſt claſs of the trap formation. It occurs in conſiderable beds, and in Sweden whole mountains are ſaid to conſiſt of it. Several mining diſtricts are ſituated in this rock, ſuch as thoſe of Gerſdorf, in Saxony, of Radolſtadt, in Sileſia, and of Adelfors, in Sweden.

Green *Sward,* in *Agriculture,* a name applied to the graſs, turf, or ſward, by which land is covered while in the ſtate of paſture or under the ſcythe. Such land as has been long in this ſtate, is moſtly covered with a cloſe compact ſward; while in the contrary caſe, it is moſtly light, open, and thin. See Sward.

Green *Turtle Bay,* in *Geography,* a ſmall iſland among the Bahamas. N. lat. 26 40. W. long. 77° 59′.

Green *Wax* is uſed where eſtreats are delivered to the ſheriffs out of the exchequer, under the ſeal of that court, made in green wax, to be levied in the ſeveral counties.

Green *Weed.* See Broom.

Green *Winter.* See Winter *Green.*

GREENAE, in *Geography,* a town of Denmark, in North Jutland; 28 miles N. E. of Aarhuus.

GREENBURGH, a townſhip of Weſt Cheſter, in the ſtate of New York, containing 1581 inhabitants.

GREENBUSH, a townſhip of Renſſelaer county, New York, containing 3472 inhabitants.

GREENCLOTH, a board, or court of juſtice, held in the compting-houſe of the king's houſhold, for the taking cognizance of all matters of government and juſtice within the king's court royal; and for correcting all the ſervants therein, that ſhall any way offend.

To this court alſo belonged the authority of maintaining the peace for twelve miles round the king's court, wherever it ſhall be, excepting at London.

The judge of this court was the lord ſteward, aſſiſted by the treaſurer, comptroller, cofferer, clerks of the greencloth, &c. It took its name, *greencloth,* from a greencloth ſpread over the board where they ſat, whereon were the arms of the compting-houſe. The clerks of this court were officers who attended there, and had buſineſs aſſigned them by the board. All bills of comptrolments, relating to the office, were ſummed up, and allowed by the clerks comptrollers, and audited by the clerks of the greencloth. They alſo appointed the king's, queen's and houſhold's diet, and kept all records, ledgers, and papers, relating thereto; made up bills, parcels, and debentures for ſalaries, &c. and proviſions and neceſſaries for the officers of the pantry, buttery, cellar, &c. They alſo waited upon foreign princes, when entertained by his majeſty. This court has been aboliſhed.

GREENE, Maurice, Dr. in *Biography,* was the ſon of the Rev. Thomas Greene, vicar of St. Olave Jewry, in London, and nephew of John Greene, ſerjeant at law. He was brought up in the choir of St. Paul, and when his voice broke was bound apprentice to Brind, the organiſt of that cathedral. He was early noticed as an elegant organ player and compoſer for the church, and obtained the place of organiſt of St. Dunſtan in the Weſt, before he was twenty years of age. In 1717, on the death of Daniel Purcell, he was likewiſe elected organiſt of St. Andrew's, Holborn; but the next year, his maſter Brind dying, Greene was appointed his ſucceſſor by the dean and chapter of St. Paul's; upon which event, he quitted both the places he had previouſly obtained. In 1726, on the death of Dr. Crofts, he was appointed organiſt and compoſer to the Chapel Royal; and on the death of Eccles, 1735, maſter of his majeſty's band. In 1730, he obtained the degree of doctor in muſic at Cambridge, and was appointed public muſic profeſſor in the ſame univerſity, in the room of Dr. Tudway. Greene was an intelligent man, a conſtant attendant at the opera, and an acute obſerver of the improvements in compoſition and performance, which Handel and the Italian ſingers employed in his dramas, had introduced into this country. His melody is therefore more elegant, and harmony more pure, than thoſe of his predeceſſors, though leſs nervous and original. Greene had the misfortune to live in the age and neighbourhood of a muſical giant, with whom he was utterly unable to contend, but by cabal and alliance with his enemies. Handel was but too prone to treat inferior artiſts with contempt; what provocation he had received from Greene, after their firſt acquaintance, when our countryman had a due ſenſe of his great powers, we know not; but for many years of his life, he never ſpoke of him without ſome injurious epithet. Greene's figure was below the common ſize, and he had the misfortune to be very much deformed; yet his addreſs and exterior manners were thoſe of a man of the world, mild, attentive, and well-bred. Hiſtory has little to do with the infirmities of artiſts; who being *men*, in ſpite of uncommon gifts and inſpirations, are ſubject to human frailties, which enthuſiaſm, praiſe, and the love of fame, more frequently augment than diminiſh.

Greene had the honour, early in life, to teach the ducheſs of Newcaſtle, which, joined to his profeſſional merit, and the propriety of his conduct, was the foundation of his favour with the prime miniſter, and the notice of the firſt people about the court. In 1730, when the duke of Newcaſtle was inſtalled chancellor of the univerſity of Cambridge, he was appointed to ſet the ode, and then not only obtained his doctor's degree, but, on the death of Dr. Tudway, he was honoured with the title of profeſſor of muſic in that univerſity. As an exerciſe for his degree, he ſet Pope's ode for St. Cecilia's day; having firſt had intereſt ſufficient to prevail on the author to make new arrangements in the poem to render it more fit for muſic, and even to add an entire new ſtanza, between the ſecond and third, which had never appeared in any of the printed editions.

Greene had ſenſe and knowledge ſufficient, in his younger days, to admire and reſpect the abilities of the two great muſical champions, Handel and Bononcini, whoſe diſputed talents occaſioned as much diſcord in the capital as the factions of Whig and Tory. At the ſame time as he was impreſſed with the higheſt reverence for Handel's great ſtyle of playing the organ, and the force of his genius for compoſition, he could not help liſtening with pleaſure to Bononcini's performance on the violoncello, and to the grace and good taſte of ſome of his opera ſongs; at which, perhaps, Handel took umbrage—for during theſe feuds, he broke off his acquaintance, and ever afterwards, regarding him as an enemy, never mentioned his name but with contempt. This treatment naturally rendered Greene a partizan on the ſide of Bononcini, and in 1728 he defended him, as long as he was able, from the charge of plagiariſm, with reſpect to a cantata which had been introduced at the academy of ancient muſic as Bononcini's, and which was afterwards diſcovered to be the compoſition of Lotti, at Venice. See BONONCINI.

Greene's merit and connections were ſuch, that he ſoon arrived at the moſt honourable appointments in his profeſſion: for beſides being organiſt of St. Paul's, in 1727, on the death of Dr. Croft, he was appointed organiſt and compoſer of the Chapel Royal; and in 1735 he ſucceeded Eccles as compoſer to his majeſty, and maſter of his band, in which ſtation he ſet all the odes of the laureate, Colley Cibber, as long as he lived.

The compoſitions of Dr. Greene were very numerous, particularly for the church. Early in his career he ſet a *Te Deum*, and part of the *Song of Deborah*, which were never printed; but the anthems and ſervices which he produced for St. Paul's and the King's Chapel, he collected and publiſhed in two vols. folio; and of theſe the merit is ſo various as to leave them open to much diſcrimination and fair criticiſm. Among the faults to be aſcribed to this compoſer, none are ſo flagrant as the light diviſions in which his ſolo anthems abound, and the repetition of paſſages a note higher or a note lower in what the Italians call *roſalia*, which are always dull, tireſome, and indications of a ſterile fancy. The opening of his ſecond ſolo anthem, vol. i. p. 26, is very ſolemn and pathetic, and the organ-part judicious and pleaſing; but, page 45, *Santa Roſalia* tells her beads ſix times, while one very ſhort paſſage is ſinging. “Lord how long wilt thou be angry,” *alla Paleſtrina*, for five voices, though none of the ſubjects are new, ſeems to us the beſt full anthem of his compoſition. The ſtyle is clear, the anſwers are regular, and the modulation ſuch as diſcovers a familiar acquaintance with the beſt ancient writers for the church. Of the full anthem: “O ſing unto the Lord,” for five voices, the fugue in the firſt movement is well worked, and has a good effect in performance; but the reſt of the anthem is not equal in its ſubjects, or their treatment. “Lord how are they increaſed that trouble me,” ſeems one of the moſt pleaſing of Dr. Greene's ſolo anthems. The laſt anthem in the firſt volume, for two voices, has many pleaſing paſſages, and rather more variety of ſubject than moſt of the others.

The firſt movement in the ſecond volume ſeems calculated to diſplay, in the performers, the power of making a ſhake upon ſhort notice. A ſhake, judiciouſly applied, is a brilliant embelliſhment in a ſinger; but when laviſhed, improperly, is pert and unmeaning; nor is it ever more ſo than upon the firſt note of a movement. There are no fewer than ſeventeen or eighteen ſhakes diſtributed among the performers in the courſe of one page, which are more than a modern opera ſinger of judgment, taſte, and expreſſion, would uſe in a month, were his ſhake ever ſo good; the reſt of the anthem is on common ſubjects, which are commonly treated.

The two-part anthem, “Thou, O God, art praiſed,” has repeatedly a paſſage on the word *praiſed*, which has to our ear the diſagreeable effect of two fifths; and there is a point at “unto thee ſhall my vow be performed,” for which he was manifeſtly obliged to the ſecond movement of Handel's fourth organ concerto. The reſt of the anthem conſiſts of agreeable paſſages of the times, but nothing like originality appears in any one idea.

“The King ſhall rejoice,” for three voices, is agreeable common-place. Perhaps that is hardly enough to ſay of the ſecond movement: “O Lord grant me a long life.”

“Let my complaint,” a full anthem, à 5, is very ſolemn and ſolid compoſition.

The anthem for Chriſtmas day has an air of chearfulneſs, ſuitable to the occaſion, which runs through the whole compoſition. “Hear my prayer, O God,” has more merit of gravity and expreſſion than moſt of the anthems in this volume. “O ſing unto God,” is agreeable muſic, but too ſecular in its melody, and return to the ſubject. “Have mercy upon me;” the two firſt movements of this anthem are ſober and affecting; but the ſecond and third have too many vulgar and worn-out diviſions; the laſt chorus, however, is more eccleſiaſtical, and leſs common in melody and modulation. The ſolo anthem: "Hear, O Lord," for a baſe voice, is grave and pathetic, on the model of Handel's beſt oratorio ſongs. The ſame may be ſaid of the next, for two voices: "I will ſeek unto God." "O God of my righteouſneſs," is ſuperior in the duet movement, ſolo verſe, and chorus, to any thing in the preceding part of this volume; this anthem riſes ſomewhat above mediocrity. "O give thanks," is wholly built with Corelli's and Handel's materials, though ſomewhat differently diſpoſed; particularly page 86, where the whole harmony moves together, one note lower, three times, after a crotchet reſt, to this baſe: E, B ※3d, E; D, A ※3d, D; C, G, C. "The Lord is my ſhepherd," has too many light ſong-paſſages in it, notwithſtanding the white and ſquare notes which give it a venerable look on paper. "O how amiable are thy dwellings," is a very agreeable anthem, though the paſſages were not new at the time it was compoſed. The movement with an organ accompaniment, in the anthem: "My ſoul truly waiteth," is well conducted, and not common; the reſt of the anthem has merit, particularly the chorus of the laſt movement. "The Lord, even the moſt mighty God," for a baſe voice, is ſet with great gravity and propriety; few anthems, indeed, for that ſpecies of voice, are more agreeable; the points, however, in the chorus, are very common. The anthem in eight parts, *à due cori:* "How long wilt thou forget me," is very well written, *à capella*, and good muſic. Indeed, the firſt movement of this anthem manifeſts greater abilities than any of his productions that we have ſeen, who is in general very correct in his harmony; but as to invention and deſign, he ſeldom ſoars above mediocrity. "O Lord give thine ear unto my prayer," for two voices, is very pleaſing muſic, particularly the firſt movement. The laſt anthem of this volume is made up of common play-houſe paſſages; the firſt movement is heavy and monotonous; the andante tireſome, by the repetitions of an old harpſichord-leſſon paſſage in the baſe; the chorus juſtifies Mr. Maſon's cenſure of the author, (collect. of the words of anthems) for his too long and frequent diviſions; theſe are too vulgar and riotous for the church, and, indeed, would have no merit of novelty any where. The *vivace*, page 151, upon which the laſt chorus is built, has more of the dancing minuet, or Vauxhall ſong, in it, than belong to that ſpecies of gravity and dignity which befits devotion. We think we could neither play nor hear this movement in a church, without feeling aſhamed of its impropriety.

There is conſiderable merit of various kinds in the Collection of Catches, Canons, and two-part Songs, publiſhed by Dr. Greene; the compoſition is clear, correct, and maſterly; the melodies, for the times when they were produced, are elegant, and deſigns intelligent and ingenious. It was ſarcaſtically ſaid, during the life of this compoſer, that his ſecular muſic ſmelt of the church, and his anthems of the theatre. The truth is, he produced but little ſecular muſic. His ſong of "Go roſe," was long in general favour, and ſome of his eaſy ballads, as "Buſy, curious, thirſty fly;" "Dear Chloe while thus beyond meaſure," &c. were the delight of ballad-mongers fifty years ago. The collection of harpſichord leſſons, which he publiſhed late in his life, though they diſcovered no great powers of invention, or hand, had its day of favour, as a boarding-ſchool book; for being neither ſo elaborate as thoſe of Handel, nor ſo difficult as the leſſons of Scarlatti, or the ſonatas of Alberti, they gave but little trouble, either to the maſter or ſcholar. Indeed, as all the paſſages are ſo familiar and temporary, they ſeem to have been occaſionally produced for idle pupils at different times, with whom facility was the firſt recommendation.

Dr. Greene, during the laſt years of his life, began to collect the ſervices and anthems of our old church compoſers, from the ſingle parts uſed in the ſeveral cathedrals of the kingdom, in order to correct and publiſh them in ſcore; a plan which he did not live to accompliſh; but bequeathing his papers to Dr. Boyce, it was afterwards executed in a very ſplendid and ample manner. Dr. Greene died in 1755, and was ſucceeded, as compoſer to the Chapel Royal and maſter of his majeſty's band, by his worthy pupil Dr. Boyce.

GREENE, in *Geography*, a county of Waſhington diſtrict in Teneſſee, containing 7610 inhabitants, of whom 471 are ſlaves. Greenville college has been eſtabliſhed by law in this county. (See GREENVILLE.)—Alſo, a county in the upper diſtrict of Georgia, bounded W. by the upper part of Oconee river, E. by Wilkes county, and S. by that of Waſhington, containing 10761 inhabitants, including 3657 ſlaves. The chief town is Greenſborough.—Alſo, a county in the ſtate of Ohio, bounded N. on the Indian ocean, S. on Roſs and Warren, E. on Roſs and Franklin, and W. on Montgomery county. Its extent from N. to S. is 58, and from E. to W. 21 miles. By the cenſus of 1803 it contains 446 white males of 21 years and upwards.—Alſo, a townſhip in Chenango county, New York, on the E. ſide of Chenango river, containing 655 inhabitants.

GREENFIELD, a handſome flouriſhing poſt-town in Hampſhire county, Maſſachuſetts, about 104 miles W. by N. from Boſton. This townſhip lies on the W. banks of the Connecticut river; it was incorporated in 1753, and contains 1254 inhabitants.—Alſo, a poſt-town in Saratoga county, New York, containing 3073 inhabitants.—Alſo, a town in Hillſborough county, New Hampſhire, containing 934 inhabitants.

GREENHILL, JOHN, in *Biography*, a painter of much promiſe, but whoſe diſſolute morals cut ſhort his thread of life, at the early age of 20. He was born at Saliſbury in 1649, and became a pupil of Lely, whoſe manner of courſe he imitated, and with much ſucceſs.

GREENHOUSE, in *Gardening*, a houſe of ſhelter in a garden; contrived for preſerving the more tender and curious exotic plants, which will not bear the winter's cold abroad in our climate.

Greenhouſes, as they are now built, ſerve not only as conſervatories, but likewiſe as ornaments of gardens; being uſually large and beautiful ſtructures, in form of galleries, wherein the plants are handſomely ranged in caſes for the purpoſe.

The greenhouſe is a ſort of building, fronted and covered with glazed frames, deſtined for the purpoſe of preſerving various ſorts of exotic ſhrubs, &c. through the winter ſeaſon: the aid of artificial heat is not here neceſſary, except in very intenſe cold weather. It is adviſeable, in conſtructing ſuch houſes, to erect flues to uſe occaſionally, which may prove ſerviceable, not only in ſevere froſts, but alſo in moiſt foggy weather, where a moderate fire will now and then dry up the damps, which would otherwiſe prove pernicious to many of the tender kinds of plants.

It differs from the conſervatory chiefly in this circumſtance, that the plants, trees, or ſhrubs, are in pots or tubs, and placed upon ſtands, frames, or ſtages, during the winter, to be removed to proper ſituations in the open air, in the hot ſummer ſeaſon; while in that there are beds, borders,

ders, and clumps, laid out in the ground plan, and made up with the beſt earthy materials, to the depth of three or four feet, in which the ſhrubs, trees, &c. are regularly planted ; the whole of the roof being removed during the ſummer to admit freſh air, and replaced on the approach of the autumn, to remain until the following ſummer renders it unneceſſary.

The green-houſes are at preſent moſtly contrived to ſtand in the pleaſure-ground, near to the houſe, if poſſible. They ſhould be upon a ſomewhat elevated ſpot, full to the ſouth, and where the ſun has acceſs from its riſing to its ſetting : theſe buildings are commonly of brick or ſtone, having the fronts and tops almoſt wholly of glaſs-work ; and ranging lengthways eaſt and weſt. They are generally conſtructed upon ſome ornamental plan. As to the general dimenſions in reſpect to length, width, and height, they may be from ten to fifty feet, or more in length, according to the number of plants to be contained ; and in width, from ten or fifteen to twenty feet ; but for middling-houſes, fifteen or eighteen feet is a ſufficient width ; and in height in the clear, nearly in proportion to the width.

The walls on the backs and ends, particularly the former, ſhould be carried up two bricks thick ; and if more than fifteen feet high, two bricks and a half thick ; at one end of the back wall on the outſide, it is eligible to erect a furnace, for burning fires occaſionally, communicating with flues within, ranging in two or three returns along the back wall, having one flue running along the front and end walls, raiſed wholly above the floor of the houſe.

The fronts of the buildings ſhould have as much glaſs as poſſible, and wide glaſs doors ſhould be made in the middle, both for ornament and entrance, and for moving in and out the plants. It would alſo be convenient to have a ſmaller entrance door at one end : the width of the windows for the glaſs ſaſhes may be five or ſix feet ; and the piers between the ſaſhes may be either of timber, ſix, eight, or ten inches wide, according to their height, or if of brick or ſtone-work, two feet wide at leaſt, ſloping both ſides of each pier inward, that by taking off the angles, a free admiſſion may be given to the rays of the ſun. For the ſame reaſon, the bottoms of the ſaſhes ſhould reach within a foot of the floor of the houſe, and their tops almoſt as high as the roof ; and if brick or ſtone piers two feet wide, ſhutters may be hung on the inſide to fall back againſt each pier. The roof may be either wholly or only half glaſs-work, next the front ; the other half ſlated, eſpecially if the upright or front piers are of timber ; and the ſhutters to cover the top glaſſes may be ſo contrived as to ſlide under the ſlated roof : where the piers are of brick or ſtone, it is common to have the roof entirely ſlated or tiled ; but ſlating is the moſt ornamental for a half or whole roof ; and the cieling within ſhould be white ; which, as well as the whole inſide wall, muſt be well plaſtered and white-waſhed, ſo as to render it clean and neat.

But in green-houſes of modern conſtruction, in order to have as much glaſs as poſſible in front, the piers between the ſaſhes are commonly of timber only, from ſix to eight or ten inches thick, according to the height, ſo as to admit as great a portion of light and heat of the ſun as poſſible, and the roofs wholly of glazed frame-work.

The green-houſes for large collections of plants have ſometimes two wings of ſmaller dimenſions, added to the main buildings, at each end, in a right line, ſeparated ſometimes from it by a glaſs partition, with ſliding ſaſhes for communication, and the front almoſt wholly of glaſs-work, and half or whole glaſs roofs. Thus, by theſe additional wings, the houſes conſiſt of three diviſions, whereby the different qualities and temperatures of the various plants can be more eligibly ſuited. The middle, or main diviſion, may be for all the principal and more hardy, woody, or ſhrubby kinds, which require protection only from froſt ; one of the wings appropriated for the ſucculent tribe, and the other to the more tender kinds that require occaſional heat in winter, but which can live without the heat of a ſtove or hot-houſe.

On whatever plans green-houſes are conſtructed, the whole of the inſide walls ſhould be neatly finiſhed off with plaſter and white-waſh, and the wood-work painted white ; the bottom being painted with large ſquare paving tiles, or ſome other ſimilar material.

In the green-houſe there ſhould be ſtands, frames, or treſſels, which may be moved in and out, upon which rows of planks may be fixed, ſo as to place the pots or tubs of plants, in regular rows, one above another ; by which their heads may be ſo ſituated as not to interfere with each other : the loweſt rows of plants next the windows being placed above four feet from them, that there may be convenient breadth left to walk in front ; and the rows of plants ſhould riſe gradually from the firſt, in ſuch a manner, that the heads of the ſecond row be entirely advanced above the firſt, the ſtems only being hid ; and at the back of the houſe a ſpace allowed of at leaſt five feet, for the conveniency of watering the plants, and to admit a current of air round them, that the damps occaſioned by their perſpiration, may be the better diſſipated ; which by being pent in too cloſely often occaſion a mouldineſs upon the tender ſhoots and leaves, and, when the houſe is cloſe ſhut up, this ſtagnating, rancid vapour is often very deſtructive ; for which reaſon they ſhould never be crowded too cloſe to each other, nor ſhould ſucculent plants ever be placed among them.

In *Plate Gardening*, (*Green-houſe*) there is a ground plan and elevation of an improved green-houſe in which *fig.* 1. ſhews the front elevation, *fig.* 2. the ground plan, and *fig.* 3. a ſection of the ſame.

And at *fig.* 4. is another houſe of this kind upon another plan.

GREEN-HOUSE *Plants*, in *Gardening*, are ſuch as require the protection of this ſort of building during the winter or other ſeaſon ; the following are the principal of the different ſorts that demand this kind of treatment.

Succulent Kind.

Agave, agave or American aloe ; compriſing common great American agave, with entire green leaves, and a branching flower-ſtalk ;—common agave with ſtriped leaves ;—Virginian agave, with narrower pale-green leaves.

Aloe, African aloe ; containing mitre-ſhaped aloe-tree, or ſword aloe ;—aloe ferox ;—fan aloe ;—ſoccotrine aloe ;—ſoap aloe ;—partridge-breaſt aloe ;—tongue aloe ;—warted-tongue aloe ;—pearl-tongue aloe ;—cobweb-aloe ;—hedge-hog aloe ;—cuſhion aloe ;—ſpiral aloe ;—pentangular ſpiral aloe ;—triangular ſpiral aloe ;—iris uvaria aloe.

Anthericum, ſpider-wort ; containing ſhrubby ſtalked, onion-leaved anthericum ;—aloe-leaved anthericum ;—mock aſphodel anthericum.

Cacalia, foreign colt's-foot ; compriſing cacalia ficoides ;—Kleinia or Indian cacalia ;—anteuphorbium cacalia ;—papillary cacalia.

Cactus, melon-thiſtle ; containing cactus opuntia, or common Indian fig.

Cotyledon, navel-wort ; containing round-leaved, long-leaved, hemiſpherical-leaved navel-wort.

Craſſula, leſſer orpine ; containing ſeveral ſpecies.

Euphorbia, euphorbium; containing moſt of the ſorts.

Meſembryanthemum, fig marigold; containing many curious ſpecies.

Sempervivum, live-ever, or houſe-leek; containing tree-houſe-leek;—variegated tree-houſe-leek;—leſſer canary tree-houſe-leek.

Herbaceous Kind.

Antholyza, Ethiopian corn-flag; containing ringent ſcarlet antholyza;—Ethiopian crimſon antholyza;—cunonia, or large ſpathed ſcarlet-flowered.

Antirrhinum, ſnap-dragon; containing variegated ſnap-dragon;—Gibraltar ſpotted flowered linaria;—Dalmatian toad flax.

Ariſtolochia, birth-wort; containing evergreen ariſtolochia;—piſtolochia, or ſmall birth-wort.

Bryonia, bryony; containing African tuberous-rooted bryony.

Calla, calla; containing ſweet calla, or Ethiopian arum.

Campanula, bell-flower; containing American bell-flower.

Canarina, canarina; containing canary bell-flower.

Canna, Indian flowering reed; containing common Indian flowering reed, and varieties;—glaucous Indian reed.

Crinum, aſphodel lily; containing African aſphodel lily;—broad-leaved aſphodel lily.

Cyclamen, cyclamen; containing Perſian cyclamen, and ſeveral varieties.

Erodium, erodium; containing pentandrous geranium or crane's bill;—thick-leaved erodium;—upright dwarf erodium.

Erythrina, coral-tree; containing herbaceous erythrina.

Ixia, ixia; containing African woolly-headed ixia;—bulbiferous ixia;—flexuous ixia;—corymbous ſpotted-flowered ixia.

Leonurus, lion's-tail; containing African ſcarlet leonurus;—ſtriped-leaved leonurus.

Ornithogalum, ſtar of Bethlehem; containing Cape ornithogalum.

Tropæolum, Indian creſs; containing double Indian creſs, or naſturtium.

Shrubby Kind.

Andromeda, andromeda; containing tree andromeda, or Carolina ſorrel.

Anthoſpermum, amber-tree; containing Ethiopian ſmooth amber-tree;—ciliated amber-tree.

Anthyllis, Jupiter's beard, or barba Jovis;—common barba jovis, or ſilver buſh;—Spaniſh ternate-leaved barba jovis;—dwarf Portugal barba jovis;—erinacea, or prickly anthyllis.

Arctotis, arctotis; containing rough-leaved arctotis;—narrow-leaved arctotis;—ſea rag-wort leaved arctotis;—plantain-leaved arctotis.

Artemiſia, mug-wort; containing tree wormwood.

Aſclepias, ſwallow-wort; containing ſhrub aſclepias.

Aſparagus; compriſing white prickly aſparagus;—declinated briſtly-leaved aſparagus;—acute-leaved aſparagus;—retrorfacted great prickly aſparagus.

Aſter, ſtar-wort; containing ſhrubby African aſter.

Aſtragalus, milk-vetch, &c.; compriſing the tragacanth, or goat's-thorn, and ſeveral varieties.

Atropa, deadly night-ſhade; containing ſhrubby deadly night-ſhade of Spain.

Baccharis, ploughman's ſpikenard; containing ivy-leaved baccharis; —oleander-leaved baccharis; —halimus-leaved baccharis.

Boſea, yerva-mora; or ſhrubby golden-rod tree.

Brunia, brunia; containing knob-flowered, or imbricated-leaved, woolly-heath leaved abrotenoides, or thyme-leaved radiated brunia.

Bubon, Macedonian parſley; containing ſhrubby galbaniferous bubon;—ſhrubby gummiferous bubon.

Buddlea, buddlea; compriſing American long-ſpiked, occidental American, globular-headed buddlea.

Buphthalmum, ox-eye; containing ſhrubby Jamaica ox-eye;—maritime, or ſea ox-eye.

Bupleurum, hare's ear; containing ſhrubby Æthiopian hare's ear;—ſhrubby difforme-leaved Cape hare's-ear.

Calendula, marigold; containing ſhrubby Cape marigold;—ſhrubby graſs-leaved Æthiopian marigold.

Capparis, caper-buſh; containing ſpinous capparis, or true caper ſhrub.

Caſſine, caſſine; containing Cape phillyrea;—Mauweema, or Hottentot cherry.

Ceanothus, ceanothus; containing African ceanothus.

Celaſtrus, ſtaff-tree; containing pyracantha-leaved celaſtrus;—box-leaved;—myrtle-leaved celaſtrus.

Ceratonia, carob-tree; compriſing common carob-tree, or St. John's beard.

Chamærops, chamærops; containing dwarf palm.

Chryſanthemum, chryſanthemum; containing ſhrubby canary chryſanthemum;—ſhrubby floſcular chryſanthemum.

Chryſocoma, goldy-locks; containing ſhrubby coma aurea, or greater African goldy-locks;—ſhrubby nodding goldy-locks.

Ciſtus, ciſtus; containing bay-leaved ciſtus;—ſea purſlane-leaved ciſtus;—and ſeveral other ſpecies.

Citrus, citron-tree; containing lemon-tree, and orange, with all the varieties of each.

Cliffortia, cliffortia; containing flea-leaved cliffortia.

Cluylia, alaternoide cluylia; containing purſlane-leaved cluylia;—elateria or Indian cluylia.

Colutea, colutea; containing ſhrubby Æthiopian ſcarlet colutea.

Convolvulus, convolvulus; compriſing evergreen canary convolvulus;—ſilvery convolvulus.

Coronilla, coronilla; containing valentine coronilla;—glaucous coronilla;—ſilvery coronilla.

Dais, dais; containing catinus-leaved dais.

Digitalis, fox glove; containing ſhrubby canary fox-glove.

Dioſma, African ſpiræa; containing oppoſite-leaved, hairy-leaved, red dioſma, &c.

Ebenus, ebony; containing ebony of Crete.

Geniſta, broom; containing ſhrubby canary broom.

Geranium, geranium; containing all the ſhrubby kinds.

Gordonia, gordonia; containing loblolly bay.

Gorteria, gorteria; containing ſhrubby prickly-leaved gorteria.

Grewia, grewia; containing occidental grewia.

Halleria, halleria; containing African-fly honeyſuckle.

Heliotropium, turn-ſole; containing ſhrubby Peruvian heliotropium.

Hermania, hermania; containing althæa-leaved, alder-leaved, lavender-leaved, gooſeberry-leaved hermania.

Hypericum, St. John's wort; containing warted-leaved Minorca St. John's wort;—Carolina St. John's wort;—China monogynous St. John's wort.

Jaſminum, jaſmine; containing Catalonian jaſmine;—Azorian jaſmine;—yellow Indian jaſmine.

Iberis, candy-tuft;—evergreen tree candy-tuft;—ever-green ſtriped-leaved candy-tuft;—ever-flowering tree candy-tuft.

Juſticia, Malabar nut-tree.

Lantana, American viburnum ; containing African lantana, or flax-leaved jaſmine ;—ſage-leaved lantana.

Laurus, bay-tree ; containing Carolina blue-berried bay ;—red-berried bay-tree ;—Indian bay-tree ;—cinnamon-tree ;—camphire-tree ;—deciduous bay-tree.

Lobelia, lobelia ; containing ſhrubby, pine-leaved, blue lobelia.

Lycium, box-thorn ; containing African box-thorn ;—Barbary box-thorn.

Malva, mallow ; containing African ſhrub-mallow medicago ; containing ſhrubby hoary medicago, or moon trefoil.

Melia, melia ; containing the bead-tree.

Mentha, mint ; containing tree-mint.

Moria, moria ; containing canaliculated-leaved moria ;—ruſh-leaved moria.

Myrica, gale, ſweet-willow, and *candle-berry myrtle ;* containing oak-leaved myrica ;—Æthiopian heart-leaved myrica.

Myrtus, myrtle-tree ; containing common myrtle, which comprehends many varieties.

Nerium, oleander, or *roſe-bay* ; compriſing common oleander, with red flowers, ſcarlet flowers, white flowers, double flowers, ſtriped-leaved.

Olea, olive tree ; containing European olive tree ;—Cape or African olive tree.

Onionis, reſt harrow ; ſhrubby Spaniſh onionis.

Oſteoſpermum, oſteoſpermum ; containing hard-ſeeded chryſanthemum.

Othonna, ragwort ; containing pectinated-leaved othonna ;—ſouthernwood-leaved othonna.

Paſſerina, ſparrow-wort ; ſhrubby African paſſerina.

Pelargonium, African geranium ; containing many ſhrubby ſpecies.

Phlomis, Jeruſalem ſage ; containing yellow phlomis, and varieties ;—purple phlomis.

Phyſalis, phyſalis ; containing alkekengi, or winter cherry ;—ſomniferous winter cherry ;—flexuous winter cherry.

Piſtacia, Piſtachia nut, and *maſtic tree ;* two or three varieties.

Polygala, milk-wort ; containing ſhrubby myrtle-leaved polygala.

Portulaca, purſlane ; containing ſhrubby Cape purſlane tree.

Poterium, burnet ; containing ſhrubby prickly burnet.

Praſium, ſhrubby hedge nettle.

Protea, ſilver-tree ; containing common ſilvery protea, or changing tree ;—coniferous protea.

Pumia, pomegranate tree ; containing dwarf pomegranate.

Rhus, ſumach ; containing African hoary ſumach, and varieties ;—African narrow-leaved ſumach, and varieties ;—ſhining-leaved African ſumach.

Royena, royena ; containing African bladder-nut.

Rumex, dock ; containing ſorrel tree.

Ruſcus, knee-holly ; containing Alexandrian laurel ;—tongue-upon-tongue laurel.

Salvia, ſage ; containing ſhrubby African golden-flowered ſage ;—ſhrubby African blue flowered ſage ;—Canary ſage ;—Mexican ſage, or ſhrubby Mexican clary.

Scabioſa, ſcabious ; containing ſhrubby ſcabious.

Senecio, groundſel ; containing ſhrubby African groundſel.

Sideritis, iron-wort ; containing Canary iron-wort ;—Cretan iron-wort.

Solanum, night-ſhade ; containing amomum Plinii ;—baſtard capſicum, or winter cherry ;—African jagged-leaved ſolanum, or pomum amoris ;—American twin-fruited ſolanum ;—thorny, downy night-ſhade.

Tanacetum, tanſey ; containing ſhrubby Æthiopian tanſey ;—under-ſhrubby ſamphire-leaved tanſey ;—tree tanſey.

Tarchonanthus, tarchonanthus ; containing ſhrubby African fleabane.

Tetragonia, tetragonia ; containing ſhrubby tetragonia.

Teucrium, germander ; compriſing Spaniſh tree-germander ;—broad-leaved tree-germander.

Vitex, chaſte-tree ; containing evergreen chaſte-tree.

Ulex, furze or *whin ;* containing African berry-bearing furze.

Xeranthemum, xeranthemum ; containing broad-leaved xeranthemum ;—narrow-leaved xeranthemum ;—trailing xeranthemum.

Yucca, Adam's needle ; containing common Adam's needle ;—thready-leaved Adam's needle ;—aloe-leaved yucca ;—dragon tree-leaved yucca.

Zygophyllum, bean caper ; containing ſeſſile-leaved bean caper ;—purſlane-leaved bean caper.

Under-ſhrubby Kind.

Dracocephalum, dracocephalum ; containing Canary dracocephalum, or balm of Gilead.

Gnaphalium, gnaphalium ; containing oriental gnaphalium, and varieties ;—ſweet-ſcented gnaphalium.

Inula, inula.

Keggelaria, keggelaria ; containing African keggelaria.

Lavateria, lavateria ; containing Cape lavateria.

Lavendula, lavender ; containing cat-leaved Canary lavender.

Lotus, bird's-foot trefoil ; containing Cretan ſilvery lotus ;—lotus Jacobæus ;—upright lotus.

Mediola, mediola ; containing climbing African mediola.

Origanum, origany ; containing dittany of Crete ;—dittany of mount Sipylus ;—Cretan marjoram ;—origany of Smyrna.

Periploca, Virginian ſilk ; containing African hoary-climbing periploca, and varieties.

Phylica, baſtard alaternus ; containing box-leaved phylica ;—heath-leaved phylica.

Phyllis, baſtard hare's ear ; or ſimpla nobla.

Polium, or *mountain poly ;* containing marum, or Syrian maſtich.

Rhamnus, buckthorn ; containing broad-leaved Indian rhamnus ;—zizyphus, or jujube.

Selago, ſelago ; containing corymb ſelago.

Smilax, rough bind-weed ; containing Chineſe rough bind-weed, or China-root ;—laurel-leaved rough bind-weed, and ſeveral varieties of each.

Stæbe, ſtæbe ; containing baſtard elichryſum.

It may be obſerved, that theſe ſorts of plants muſt conſtantly be kept in pots, and ſome large kinds in tubs, for moving into ſhelter in winter, and into the open air in ſummer ; as, being all exotics from various warm parts of the world, they are of tender growth in this climate, and conſequently not able to live in the open air in the winter months.

And the pots and tubs for containing them muſt be of different ſizes, according to the ſize and nature of the plants, which, as they advance in growth, ſhould have large pots, &c. provided for them accordingly ; and when they become wholly too large for the pots, they muſt be ſhifted into tubs hooped with iron, with two iron handles to each at the top-part.

It is neceſſary in potting or planting the different ſorts, care ſhould be taken that the pots or tubs have holes at bottom for the diſcharge of redundant moiſture, each hole being covered with a piece of tile or oyſter-ſhell before the mould is put in, to prevent their being ſtopped up, and the earth from being waſhed out below.

The beſt modes of propagating the different ſorts, the nature of the earth in which they ſucceed beſt, and the ſeaſon moſt proper for raiſing them, are fully explained under the culture of the reſpective kinds, and may be ſeen under their proper heads.

General Method of Management of Green-houſe Plants.—As moſt plants of this ſort are capable of bearing the open air from the latter end of May till October; but the reſt of the year demand the protection of the green-houſe, they, of courſe, require to be ſet out into it as ſoon as the weather begins to be ſuitable, in the ſpring and ſummer months; eſpecially for ſuch as all the ſeveral varieties of myrtles, geraniums, oleanders, ciſtuſes, phlomiſes, ſhrubby aſter, tree-wormwood, tree-candy-tuft, yellow Indian and Spaniſh jaſmines, Indian bay, &c &c. And this ſhould be done in the laſt week in May, or firſt in June, according as the ſeaſon proves more or leſs favourable for all the other ſorts: but it ſhould not be attempted till the ſeaſon is become perfectly ſettled, and there is a fair proſpect of ſummer being arrived, as there are often very cold nights and frequently froſty mornings in May, and even in the beginning of June, which, if the plants were fully expoſed, would pinch the ends of their young ſhoots and leaves, and greatly injure them. A mild warm day ſhould be choſen for this work; and if a warm rain, it will be of much advantage, as it waſhes the leaves and branches from the duſt they have contracted, and greatly refreſhes the plants that are thus expoſed to it.

Method of Setting out the Plants.—This is done in the more hardy ſorts in thin pots about the middle of May.

When firſt brought out, it is proper to place them in ſome ſheltered ſunny place, for a fortnight, till they are inured to the open air; then to ſet them in any open expoſure, where they are to remain for the ſummer. And as ſoon as they are brought out, they ſhould be cleared from all dead leaves, and all dead wood; and the earth on the ſurface of the pots be ſtirred, taking a little of the old out, and adding ſome freſh mould in its ſtead, which will prove very beneficial; then give moderate watering, not only to the mould, but alſo over the heads of the plants, to clear them effectually from all dirt and filth which they have contracted in the green-houſe during the winter.

In putting them out, they may be placed according to the fancy of the proprietor; ſome of the handſomeſt plants being occaſionally placed to adorn ſpacious fore-courts, or arranged on each ſide of large walks contiguous to the main habitation; and others near ornamental garden-buildings; they are alſo ſometimes diſpoſed in groups, or ſmall clumps in the moſt conſpicuous places, in different parts of the pleaſure-ground; exhibiting different ſorts in each group, in order to cauſe the greater variety and effect in ſuch ſituations.

As ſoon as they have been thus placed out, their chief culture is, to ſupply themplentifully with water during the ſummer ſeaſon, in hot dry weather: all the woody or ſhrubby kinds in particular; likewiſe the herbaceous kinds that are not very ſucculent, require it three times a week at leaſt: and in a very hot dry time once every day. The ſucculent kinds muſt alſo have a moderate ſupply of water two or three times a week in dry weather; the proper time for watering all the ſorts at this ſeaſon is, either in a morning before nine o'clock, or in the afternoon about four or five; for, if performed in the middle of the day in ſummer weather, the ſun would exhale a great part of the moiſture before it effected its intended operation on the fibres of the plants: this buſineſs ſhould be duly attended to in dry weather. As the mould roots, and fibres of the plants are circumſcribed within the narrow limits of a pot or tub, the earth, as well as the fibres, dries very faſt in ſummer, and neceſſarily requires frequent refreſhments of water, to preſerve that due and conſtant degree of moiſture which is requiſite for the ſupport of healthy vegetation in the different plants.

Even moderate rains ſhould not prevent watering occaſionally, eſpecially ſuch plants as have ſpreading heads, which prevent the rains, unleſs very heavy or conſtant, from falling in ſufficient quantities on the earth of the pots, to moiſten it properly. And in hot weather, if ſome mowings of ſhort graſs are ſpread on the ſurface of the orange-tree tubs and others, it will greatly preſerve the moiſture. During this ſeaſon, it will alſo be a good practice to looſen the ſurface of the earth now and then in ſuch pots and tubs as have a tendency to bind or become ſtiff by time.

Manner of taking in the plants.—About the beginning of the autumn, as towards the latter end of September, the more tender kinds of theſe exotic plants muſt be removed into the houſe; the ſucculent tribe, in particular, ſhould be removed to ſhelter at the firſt approach of exceſſive wet and cold nights. The oranges, lemons, and all the other ſpecies ſhould be moved into ſhelter in due time, either in the end of September or early in October; for, if they are permitted to remain in the open air till attacked by ſharp weather, it changes the beautiful verdure of their leaves to a ruſty yellow hue, which they do not recover during winter; therefore, about the latter end of September, or beginning of October at lateſt, the principal plants ſhould be brought in; the ſucculent and others of a more tender temperature, as early in the former month as the cold weather begins to come on; and continue moving in all the others as the cold increaſes; and by the middle of October have the whole collection in the houſe. As the time approaches for moving in the different ſorts, clear them perfectly well from decayed leaves, &c. all the pots being well cleaned, looſening the ſurface of the earth in each pot, and adding a little freſh mould. As the different ſorts are brought occaſionally into the green-houſe, they may be placed promiſcuouſly till the whole are in, and then be arranged regularly, as they are to remain for the winter; leaving all the windows quite open till that time. When the whole is brought in, they ſhould be diſpoſed in regular order, ſo as to appear to the beſt advantage, both in reſpect to their general arrangement and variety, and ſo as each may have an equal portion of ſun and air; the talleſt plants being arranged in the back, the others in their ſeveral ranks, according to their degrees of height, gradually down to the loweſt in front; and as there is a vaſt variety both in ſize, ſhape, and colour, of the foliage, they ſhould be diſpoſed ſo as to ſet off each other and give a pleaſing variety to the whole; and if poſſible, they ſhould ſtand clear of one another; by which each plant will be ſeparately conſpicuous, and the whole exhibit a greater air of freedom and variety, as well as admit an equal portion of ſun, and a more free circulation of air among them.

When the plants have been thus collected in, their principal culture is the ſupplying them with freſh air at all opportunities in mild weather, and giving moderate waterings occaſionally, picking off decayed leaves, cutting out caſual decayed ſhoots, and making occaſional moderate fires in ſevere weather, alſo, ſometimes to diſpel great damps and noxious fogs from them.

With reſpect to giving air, it ſhould be admitted every mild, calm day, by opening the windows more or leſs, according to the temperature of the weather. When the plants are firſt houſed, they ſhould have as much free air as the nature of the ſeaſon will admit, by opening the windows every mild day to their full extent ; and if the air is quite temperate, they may remain open in the nights for the firſt week ; but in cold nights they ſhould be conſtantly ſhut ; this work of admitting air muſt be conſtantly attended to all the winter ; for, without a due portion of this eſſential article in mild weather, the plants ſoon loſe their fine verdure and aſſume a ſickly yellowiſh colour, become diſeaſed, and the young ſhoots, in many ſorts, grow mouldy and rot off, and the leaves of the plants drop ; therefore, never omit every mild day, when not very damp or foggy, to open ſome or all of the windows little or much, according as the air is more or leſs temperate ; the proper time during winter for this, is from about eight, nine, or ten in a morning, till three, four, or five in the evening, according to the mildneſs of the day ; but as the days lengthen and the warm weather increaſes, give more air in proportion, earlier and later in the day as may be judged proper, being careful always to ſhut all cloſe in due time every evening, as ſoon as the ſharp air approaches. In foggy weather, it is adviſable to keep the windows quite cloſe ; for the great damps occaſioned by fogs are very pernicious to theſe plants whilſt they are confined in the houſe ; alſo, when boiſterous or cold cutting winds blow towards the front of the green-houſe, the whole ſhould be kept ſhut ; or only, if thought neceſſary, ſome of the upper ſaſhes drawn down a little way at top, above the reach of the wind ruſhing immediately upon the plants ; likewiſe, in all froſty weather, the houſe ſhould be kept cloſe, except the froſt is moderate, and the middle of the day ſunny and warm, when ſome of the windows may be opened a little, but ſhut cloſe again if the ſun is clouded, and at any rate before the air changes cold : in ſevere weather, the ſhutters, &c. ſhould be ſhut every night, alſo, occaſionally when the froſt is extremely rigorous and no ſun ; and likewiſe, in ſuch weather, the aſſiſtance of fire-heat as hereafter directed may be neceſſary. As the ſpring approaches, and the weather grows warmer, enlarge the portion of air accordingly, admitting it alſo both earlier in a morning and later in the evening as the days lengthen ; for then the plants will aſſume a growing ſtate, and a conſiderable portion of air is requiſite every mild day, both to ſtrengthen the new ſhoots and inure the plants by degrees to the air againſt the time for removing them fully into it again for the ſummer ſeaſon.

And watering will alſo be neceſſary to moſt of the ſorts, but muſt be afforded them as ſparingly as poſſible during the winter months, and ſcarcely any ſhould be given when the houſe is obliged to be ſhut cloſe through the ſeverity of the weather : there are no certain rules to be given for the application of this ; ſome plants require only a little water once a week, or ten or twelve days in mild weather, ſuch as the orange and lemon trees, myrtles, oleanders, ſhrubby-geraniums, and other woody kinds ; all that is neceſſary being juſt to preſerve the earth very moderately moiſt ; the pots and tubs muſt therefore be examined with proper attention, and water given to ſuch only as are in want. The herbaceous kinds ſhould be rather more ſparingly watered than the ſhrubby ſorts ; and all the ſucculent tribe have water but ſeldom, ſome not oftener than once a fortnight or three weeks, and that always but very ſparingly at each time ; and ſome that are very ſucculent require but very little from November till March ; indeed all the ſucculents ſhould only have it now and then at this ſeaſon, when the earth in the pots becomes very dry and hard.

In executing the buſineſs of watering in general, care ſhould be particularly taken to do it with great moderation at the time the plants are in the green-houſe, as when you once over-wet the earth at this ſeaſon, it will continue in that ſtate for a long time, and by chilling the tender fibres of the roots of the plants, often cauſe the loſs of the leaves of many of them, and even the death of ſome kinds. In a ſunny day, from about eleven o'clock to two, is the moſt proper time for having this ſort of work done.

Soft water, if poſſible, ſhould be uſed, or at leaſt ſuch as had been expoſed to the air two or three days, as freſh ſpring water is much too cold : and during froſty weather great attention is requiſite to keep all the windows cloſe, night and day, unleſs when very moderate, as juſt obſerved, and the middle of the day is ſunny and warm ; when ſome part of the houſe may be opened a little for two or three hours, having particular regard to ſhutting all cloſe in due time in the afternoon, before the air changes to become ſharply cold : but in very ſevere froſts it muſt be kept cloſe night and day, and the ſhutters or other covers of canvaſs or mats be alſo uſed every night ; alſo, occaſionally in the day time, when the weather is intenſely ſevere, and no ſun appears, and there are no flues for fires to keep out the froſt. The ſhutters, or other ſhelters, beſides the glaſſes, ſhould however be uſed as little as poſſible in the day-time, except in caſes of particular neceſſity, as every opportunity ought to be taken for the admiſſion of light and freſh air, as much as the temperature of the weather will poſſibly admit, as moſt of the plants only want protection from froſt and the common ſhelter of the houſe, which, with ſhutting the ſaſhes cloſe every night, will be ſufficient for the purpoſe.

In caſes where there are flues for fires, it will be adviſeable to make moderate ones at ſuch times as the froſt cannot be otherwiſe kept out, eſpecially on nights ; but this muſt by no means be continued longer than is neceſſary to guard againſt very ſevere froſts and the danger of the plants.

In very cold, foggy, damp weather, a moderate fire now and then in the flues alſo proves very beneficial in expelling the damp unwholeſome vapours, ſo pernicious to all plants of this nature. Whilſt the plants are in the houſe, all decayed leaves, &c. ſhould likewiſe be conſtantly picked off, being neceſſary both to preſerve the beauty and health of the plants. The decayed leaves of the ſucculent kinds ſhould be cut off cloſe with a ſharp knife ; the plants in general ſhould likewiſe be occaſionally cleaned from any filth they may contract in the houſe, ſuch as duſt, cobwebs, &c.

General Method of Culture of the Plants.—Theſe ſorts of plants generally want ſhifting into larger pots and freſh earth as they advance in growth ; ſuch as are faſt growers, as ſome of the ſhrubby geraniums, &c. annually, or every other year ; and ſome plants in large pots, &c. once in two or three years, and others not ſo often, eſpecially ſome large-grown American aloes, orange and lemon-trees, and thoſe in large tubs, having a conſiderable ſubſtance of earth about the roots. Sometimes theſe and other ſimilar kinds, when not convenient to ſhift them, have the top earth, and a little down round the ſides, looſened to ſome moderate depth in the ſpring, removing the looſened ſoil, and filling the ſpace up with freſh compoſt. But as the plants in general increaſe conſiderably in proportion to their nature of growth, ſhifting into larger pots or tubs, with ſome freſh earth, ſhould not be omitted occaſionally as it may ſeem neceſſary, as it proves beneficial to moſt of the ſorts. They may moſt of them be ſhifted with the ball of earth about their roots entire ; but others, that are weak and ſickly, require ſhifting into entire freſh earth prepared for the purpoſe.

The moſt proper time for ſhifting all the ſorts is in April, ar before they are removed into the open air for the ſummer; but it may be occaſionally done in autumn, as in Auguſt or the beginning of September, in time to ſtrike freſh root before winter. In the work of ſhifting, each plant ſhould be drawn out of its pot or tub with the ball of earth about its roots entire, then all the dry matted fibres round the outſide of the ball pared off and cleared away, alſo, ſome of the old earth at the ſides, bottoms, and tops: then having the new pots and freſh earth ready, the holes at the bottoms of the pots ſhould be covered with pieces of tiles or oyſter-ſhells, and ſome of the freſh earth put in; placing the plant in the pot, and filling up the vacancy all round with more freſh compoſt, bringing it an inch over the top of the ball, giving a good watering to ſettle the earth cloſe in every part: after this, it is neceſſary to place the plants to have ſhade from the mid-day ſun for a week or fortnight, and ſometimes longer.

All ſuch plants as are become of a weak ſickly nature ſhould, at ſhifting, have all the earth taken clean from about their roots, having them waſhed, and then planted into entire freſh earth properly prepared for them.

And the larger ſorts of plants, ſuch as the orange-trees, lemons, citrons, American aloes, and others of ſimilar growth, ſhould be ſhifted, when large, from pots into tubs hooped with iron, having two iron handles at top, as obſerved above, for the convenience of lifting them in and out of the green-houſe, as they ſometimes grow to ſo large a ſize as to require two and ſometimes three or four men to move them.

But all ſuch plants as are not ſhifted annually ſhould, in ſpring, have the earth in the tops of the pots or tubs looſened to a little depth, alſo, a little way down round the ſides, taking the looſened earth out; and in its ſtead adding a quantity of freſh mould, giving it directly a little water to ſettle it cloſe. This ſhould never be omitted when neceſſary. At any time when the ſurface of the earth is obſerved to be ſtiff, whether in the ſhifted or unſhifted plants, it is of much ſervice to ſtir it an inch in depth occaſionally, and add a little freſh compoſt when neceſſary to the plants.

And the mould or compoſt into which the plants are to be ſhifted is of conſiderable importance. The beſt is obtained from commons where ſheep and cattle paſture, particularly in low places, where the fineſt graſs grows and the ſoil is deepeſt. A foot of the top ſoil with the turf ſhould be taken off, and, if a ſandy or hazel loam, it will do alone; but if a ſtrong loam, ſome ſand and black peaty, boggy, or mooriſh ſoil ſhould be added. Such ſoils ſhould be laid in a heap ſix winter months or more, and frequently turned over. Some plants, as aloes, meſembryanthemums, ixias, and exotic liliaceous plants in general, require a ſoil which is a degree lighter, and which does not retain the water, but lets it paſs readily. A little coal-aſhes at the bottom of each pot is uſeful in this view as well as others.

Moſt of the ericas, or heaths, and other beautiful plants from the Cape of Good Hope, from America, and Botany Bay, delight and flouriſh in this ſort of earth, which comes neareſt to their native ſoil: thus, the heaths like a black peat or mooriſh ſoil; and the others, that which is made a degree ſtronger, with loamy earth intermixed with it.

It is neceſſary to keep the heads and every part clean from duſt and other filth, by occaſionally waſhing with water all the ſorts, which in moſt is done by waterings over their heads; but in others, when very foul, by waſhing their leaves with a ſponge and water, eſpecially in winter. This is often neceſſary to the oranges and lemons, and other large-leafed kinds of plants that have been mentioned.

Where the heads of any of the ſhrubby kinds are become very irregular or ſhabby, the branches may be pruned ſhorter or longer, as neceſſary, in the early ſpring months.

And where any of the principal exotics aſſume a declining ſtate, ſuch as oranges, lemons, &c. or have thin, ſtraggling, weakly heads, or are apt to drop their leaves, it is proper either to ſhift them wholly, or apply ſome freſh earth to their roots, and then prune the heads moderately cloſe in the early ſpring, plunging them in a bark-pit under glaſſes. The heat of the bark-bed ſo greatly revives their growth, that they break forth into many ſtrong new ſhoots, and form handſome renewed full heads in the ſummer ſeaſon.

While in the green-houſe, ſome plants drop all their leaves, either by the effects of cold or over-watering, or ſometimes by being kept too long in too dry a ſtate, as frequently occurs in myrtles and geraniums, and ſometimes oranges, lemons, and others; in which caſe it is proper in the ſpring to prune the heads, ſhortening the long ſtrong ſhoots and branches, and to ſhift them with balls into freſh earth, or, if not ſhifted, to looſen the earth in the tops and ſides of the pots, drawing out the looſened mould, and ſupplying the place with freſh. They afterwards ſoon puſh forth into young ſhoots and leaves, and renew their heads with verdure. Sometimes myrtles, geraniums, &c. in this ſtate, when headed, may, on being brought forth in the ſummer, be drawn out of the pots, and plunged in the ground in a ſheltered ſituation, and watered in dry weather; when they will ſend their roots into the full earth and break forth ſtrongly at top into young wood and foliage, and form full heads, being then re-potted with balls of earth to the roots.

But the heads of green-houſe plants ſhould never be clipped with garden-ſhears, nor, by any mode of pruning, trimmed into any formal figure, as ſometimes practiſed; but every ſort be let aſſume its own natural growth, only juſt uſing the knife to regulate any very irregular or rambling ſhoot or branch, or to thin out ſome where too much crowded, and to cut out the dead wood they may contain in any part of them.

GREENLAND, in *Geography*, comprehends a peninſula generally allowed to be attached to North America, and a number of detached iſlands, ſituated in high northern latitudes; the former is called *Weſt* or *Old* Greenland, and the latter *Eaſt* or *New* Greenland, and more commonly Spitzbergen.

Weſt or Old Greenland, is now generally believed to be a peninſula, connected in its north-weſtern parts, hitherto unexplored, with America. The reaſons alleged for ſuppoſing that the N. W. ſide is contiguous to America, and actually attached to it are the following: Davis's ſtrait, or Baffin's bay, it is ſaid, becomes narrower and narrower towards 78° N. lat.; the coaſt alſo, which in other places is very high towards the ſea, gradually lowers northward; and the tide, which at Statenhook, and even as far as Cockin's ſound, in the 65th degree, riſes 18 feet at the new and full moon, decreaſes ſo much in the north above Diſko, that in the 70th degree it does not riſe much above eight feet, and probably loſes itſelf entirely at laſt. Hence captain Baffin gave up all hopes of finding a paſſage into the South ſeas through Davis's ſtraits, and conſequently concluded, that Greenland joined with America. The Greenlanders report, though much dependance cannot be laid upon their information, that the ſtrait at laſt becomes ſo narrow, that they can approach the other ſide ſo nearly, as to be able to call to the inhabitants, and ſtrike a fiſh from both ſides at once: but they affirm, that a ſtrong current runs from the north into the ſtrait, which prevents their coming to one another.

The name Greenland was given to the eaſt ſide of this territory many hundred years ago by the Norwegians and Icelanders, who are ſaid to have firſt diſcovered it, becauſe its appearance was *greener* than that of Iceland. But this eaſt ſide, ſometimes called *Old* or *Loſt* Greenland, is now almoſt totally unknown, becauſe ſhips cannot navigate this coaſt, on account of the great quantities of floating ice. Weſt Greenland lies between the ſtraits of Davis and Frobiſher, and Iceland, and is bounded on the W. by Baffin's bay, on the S. by Davis's ſtrait, and on the E. by the northern part of the Atlantic ocean; but its northern boundaries are unknown. It reaches from the ſouthernmoſt point of Cape Farewell, and Statenhook, in the 59th degree, on the right ſide north-eaſtward, towards Spitzbergen, to the 80th degree; and on the left ſide oppoſite to North America, N. W. and N. till about the 78th degree; the coaſts having been ſo far diſcovered. Moſt of the Greenlanders live from Statenhook to the 62d degree, or, as the inhabitants ſay, in the ſouth; but as no Europeans live there, theſe parts are imperfectly known. The interior of this dreary country is extremely mountainous, and ſome of the mountains are ſo high that they may be diſcerned at the diſtance of 40 or 60 leagues. This is particularly the caſe with that which is the higheſt mountain in the country, called "Hiorte-tak," or ſtag's-horn. It has three branches or points, the moſt lofty of which ſerves as a ſea-mark to navigators, and alſo as a weather-gage, for when a ſtorm is approaching from the ſouth, the ſummit of this mountain is enveloped in a ſmall miſty cloud. The hills and rocks of this country are covered with perpetual ſnow; though the low lands on the ſea-coaſt are clothed with verdure in the ſummer ſeaſon. The ice and ſnow, like the glaciers of Switzerland, fill the elevated plains, and even many vallies. The coaſt is indented with many bays and creeks that enter far into the land: and it is encompaſſed with innumerable large and ſmall iſlands, and both viſible and imperceptible rocks. The ſhore, however, is in many places inacceſſible on account of the floating mountains of ice. This country is ſaid to have been diſcovered by ſome emigrants from Iceland: the diſtance, according to the beſt maps, being about 8° of longitude, in lat. 66°, or nearly 200 geographical miles, though ſome maps reduce it to 5°, or not more than 130 geographical miles. The diſcovery was accidentally made by Eric Raude, or the red-headed, who being exiled from Iceland on account of the murder of one of its chiefs, found this country; and, coaſting along the S. W. border, wintered at an agreeable iſland near a ſound, which he called Eric's ſound. Having in the following year examined the main land, he returned in the third year to Iceland: and in order to induce the inhabitants of Iceland to accompany him he called it Greenland, expreſſing its verdant appearance, and repreſented it as abounding with paſture, wood, and fiſh. The effect of his repreſentation was ſuch, that in the ſucceeding year he was followed by twenty-five ſhips full of coloniſts, who had furniſhed themſelves richly with houſehold goods and cattle of all ſorts: however, only fourteen of theſe ſhips arrived ſafe: but in proceſs of time more colonies flocked to Greenland, both on the eaſt and weſt ſide, from Norway as well as Iceland. Torfæus, a native of Iceland, in his "Groenlandia Antiqua," dates the diſcovery of Greenland in the year 982. But it has been inferred from a bull iſſued by pope Gregory IV. in 835, and which commits the converſion of the northern nations, and in expreſs words, of the Icelanders and Greenlanders, to the firſt northern apoſtle Anſgarius, (if this bull be indeed authentic,) that Greenland muſt have been diſcovered and planted about the year 830, by the Icelanders and Norwegians. Leif, the ſon of Eric Raude, is ſaid to have made a voyage to Norway, A. D. 999, to give the king, Olaus Tryggeſon, an account of the new colony in Greenland; and this king, having juſt renounced heatheniſm, converted Leif, and perſuaded him to be baptized, and to take with him to Greenland a prieſt, for the converſion of the inhabitants. Upon his return his father was induced to embrace Chriſtianity, and the reſt of the colony followed his example. In the year 1122 they choſe Arnold, a Norwegian, for their biſhop; and he fixed his epiſcopal reſidence at Gardar. In the year 1261, they, and the Icelanders, ſubjected themſelves voluntarily under the Norwegian ſceptre; and from that time they were governed by a king's deputy from Norway, according to the laws of Iceland; and when an archbiſhopric was erected at Drontheim in Norway, the Greenland biſhops became ſuffragans to this metropolitan. The intercourſe between this colony in Greenland and Norway continued, with little interruption, till the beginning of the 15th century; the laſt of 17 biſhops being appointed in the year 1406. During this period the Greenland trade is ſaid to have been very conſiderable; and it is very probable that they exported a large quantity of fleſh, butter, cheeſe, fiſh, train, and pelts, chiefly by means of foreign ſhips; for though the Norwegian ſettlers in Greenland, upon their firſt eſtabliſhment, ſailed in their own veſſels from Iceland and Norway to this country, they afterwards very much neglected navigation. After the period above-mentioned Greenland ſeems to have been little regarded, and its intercourſe with other countries almoſt wholly ceaſed. In order to account for this ſudden change of condition, it ſhould be conſidered, that the firſt ſettlers were very much haraſſed by the natives, who were a barbarous and ſavage people, and who reſembled, in their cuſtoms, garb, and appearance, the Eſquimaux found about Hudſon's bay. Theſe people were denominated "Skrællings," or "Korralit," an appellation aſſumed by the Eſquimaux. The Daniſh Chronicle, a work written in verſe, and, indeed, of doubtful authority, though cited by Torfæus, informs us, that certain Armenians were firſt driven hither by a ſtorm, and that from hence they peopled Norway and America, and that many tribes were found in Greenland, who were governed by different chiefs. The Skrællings, it is ſuppoſed, and not without ſome degree of probability, firſt came to Greenland in the 14th century, not from the eaſt out of Europe, but from the weſt out of North America. But their origin is traced to the N. E. regions of Great Tartary, between the Ice-ſea (mare glaciale) and Mungolia. They firſt came into Tartary, after the great diſperſion of the nations, and were driven on further and further by imperious or more potent nations that followed them, till at laſt they were compelled to withdraw into the remoteſt corner of Tartary near Kamſkatka, and from hence they migrated to America; extending themſelves round the S. E. part of Hudſon's bay, or through Canada as far as the North ſea: and here, it is ſuppoſed, they were firſt found by the Norwegians in the 11th century. Dreading and wiſhing to avoid the moleſtation which they ſuffered from the other Indians, theſe fugitives retreated northwards, till, probably, in the 14th century, they either croſſed Davis's ſtraits in their boats, from Cape Walſingham, in the 66th degree, to the South-bay in Greenland, which can be ſcarcely 60 leagues wide; or elſe they went higher up by Baffin's bay, and ſo came down on the parts where the Norwegians formerly had their habitations, firſt on the weſt ſide, and then by degrees round to the eaſt. Theſe Skrællings are ſuppoſed to have exterminated the Iceland and Norwegian ſettlers who inhabited the weſtern diſtrict, in the 14th century; after they had been previouſly diminiſhed in number, or very much enfeebled by a peſtilence, which raged about the year 1350. On this occaſion the Norwegians were driven from the weſt to the eaſt ſide, ſo that the weſtern parts of Greenland were wholly occupied by theſe Skrællings. Some of them blended themſelves with their conquerors, and others of them receded farther northwards into the inlets between the mountains. The ancient ſettlement contained ſeveral churches and monaſteries, from which it would ſeem that the colony extended over about 200 miles in the ſouth-eaſtern extremity. On the weſt ſome ruins of churches have been alſo diſcovered. In the eaſtern diſtrict, as we have reaſon to imagine, there are ſome remains of the ancient colony, though no intercourſe can be maintained between the inhabitants of both ſides of the country, on account of high mountains, perpetually covered with ſnow, which ſeparate the two parts of Greenland; and the navigation from one to the other is impeded by the mountains of ice, that are driven ſouthward from Spitzbergen, or Eaſt Greenland. From authentic records we can derive little information that is ſatisfactory, or upon which we can rely. From ſome of the moſt credible we learn, that Greenland was divided into two diſtricts, called "Weſt Bygd," and "Eaſt Bygd;" the former contained four pariſhes, and 100 villages; but the latter was more flouriſhing, as it is nearer to Iceland, and was ſooner ſettled, and alſo more frequented by Norwegian navigators. The colony that firſt ſettled in the eaſt, of which we have already given an account, is ſaid to have comprehended, in ancient times, 12 extenſive pariſhes, 120 villages, a biſhop's ſee, and two monaſteries. The preſent inhabitants of the weſtern diſtrict are ſeparated from thoſe of the eaſt by impaſſable deſerts and mountains, ſo that they know little of one another; excepting that the eaſtern Greenlanders are thought by thoſe of the weſt to be a cruel and barbarous nation, that deſtroy and eat all ſtrangers that fall into their hands. For about a century after the ceſſation of intercourſe between the Greenlanders and other nations, they were very much neglected; all the attempts made by the kings of Denmark to explore the eaſtern diſtrict having miſcarried. At length, in the year 1578, Frederic II. ſent the famous navigator, Magnus Henningſen, who, having encountered much danger from ſtorms and ice, and gained ſight of land, was obliged to return, probably on account of ſome unfounded apprehenſions which deterred him from proceeding farther. About two years before this event, *viz.* in 1576, queen Elizabeth ſent out Martin Frobiſher to find a N. W. paſſage to China; he diſcovered land, which he named "meta incognita," and particularly the ſtraits which bear his name; and traded with the Indians. On his return he brought with him a black ſtone, from which gold was extracted. In the year 1578 he was ſent out again with a view of eſtabliſhing a colony in Greenland, but he returned, after a ſtormy paſſage and ſeveral diſaſters, with as much of the mineral earth or ore as he could procure, and the deſign was never proſecuted. Frobiſher was followed, in the year 1585, by John Davis, who ſailed as high as N. lat. 64° 15′, *i. e.* to Ball's river, where he landed and traded with the natives. Then, and in the two following years, he diſcovered the coaſts of America as high as the 70th degree, and gave the ſtraits his own name. In the year 1605, Chriſtian IV., king of Denmark, ſent the Daniſh admiral Godſke Lindenow, accompanied by John Knight, an Engliſh mariner, to reconnoitre the coaſts of Greenland: the inhabitants on the weſt ſide were found to be much wilder than thoſe on the eaſt ſide, nor did they at all reſemble one another in their language, dreſs, and manners. Voyages of a ſimilar nature were repeated, but no permanent advantage reſulted from them.

At length, in the year 1721, a pious clergyman of Norway, Hans Egede, having long lamented the wretched condition of the Greenlanders, through the want of religious inſtruction, as well as a variety of worldly comforts, and having projected, from the year 1708, ſchemes for their relief, without effect, determined to relinquiſh his church preferment, and to make a voyage to Greenland, with a view of accompliſhing his benevolent intentions. After having collected a capital of about 2000*l.*, by various ſubſcriptions, and obtained from the king an appointment of miſſionary, with the yearly ſalary of 60*l.*, beſides a preſent of 40*l.* towards his equipment, Mr. Egede placed himſelf at the head of a colony of 40 perſons, and ſailed for Greenland. Theſe adventurers, having paſſed Statenhook, encountered many dangers from ſtorms and ice, happily landed at Ball's river, N. lat. 64°, on an iſland near Kangek, which they called after the name of the ſhip in which they had ſailed, "Haabats-Oe," *i. e.* Hope iſland. They were hoſpitably received by the natives, and Mr. Egede took great pains, by his condeſcending attention, and by the aſſiduity with which he communicated to them religious inſtruction, to conciliate their friendly attachment. He alſo took great pains to acquaint himſelf with the language of the country, and to diſcover the beſt places for hunting and fiſhing, ſo as moſt effectually to ſerve the convenience of the colony. He made repeated attempts for exploring the eaſtern ſide of the country, and for diſcovering Frobiſher's ſtraits, but the wind and ice rendered his efforts unſucceſsful. As a miſſionary, he diſcharged the truſt which he had undertaken with ſingular fidelity, diligence, and zeal, and having continued in this inhoſpitable region till the year 1736, he returned to Denmark with a debilitated conſtitution. He was ſoon after appointed ſuperintendent of the miſſion in Greenland, with a ſalary of 100*l.* per annum, and was ordered to found a ſeminary of ſtudents and orphans, whom he was to inſtruct in the Greenland language, and who were to ſupply a ſucceſſion of miſſionaries and catechiſts. He ſpent his latter years in a receſs with his daughter, on the iſland of Falſter, and there cloſed his life of ſervice and honour, November 5th, 1758, in the 73d year of his age. To him and to his ſon, Paul Egede, we are indebted for the moſt ample and authentic account of modern Greenland. The example of Mr. Egede has been ſince followed by ſeveral miſſionaries, particularly from among the Moravians, whoſe principal ſettlements were at Kangek, New Herrnhuth, and Lichtenfels. From Mr. Egede we learn that the moſt practicable method of reaching the eaſtern part of Greenland will be to coaſt north about in ſmall veſſels, between the great flakes of ice and the ſhore; the Greenlanders having always declared, that the currents, which ruſh from the bays and inlets, and run ſouth-weſtward along the ſhore, hinder the ice from adhering to the land, ſo that there is always a channel open, through which veſſels of ſmall burden may paſs, eſpecially if lodges were built at convenient diſtances on the ſhore, for the accommodation and direction of the adventurers. The part of the country that is now viſited by the Danes and Norwegians, lies between the 64th and 68th degrees of N. latitude, and ſo far the climate is found to be temperate. We are told, however, that the country is inhabited as far as 76°; but the Daniſh and Moravian ſettlements are chiefly in the ſouth-weſt, though at one time there appears to have been a factory as far north as 73°.

In the ſummer, from the end of May to the middle of September, the weather is warm and comfortable, when the wind blows from the eaſt: though violent ſtorms then occur, and the fogs on the ſea-coaſt are inſalubrious. The land near the ſhore exhibits a pleaſing verdure, but the inland mountains are perpetually covered with ice and ſnow. Beyond the 68th degree of latitude the cold is very intenſe, ſo that the rocks often burſt by the froſt; and towards the end of Auguſt, the whole coaſt is covered with ice, which never thaws till April or May, and ſometimes not till the latter end of June. The prodigious maſſes of ice that ſurround the whole coaſt exhibit an appearance, in calm weather, no leſs dazzling than dreadful, by the reflection of the ſun-beams in its variety of colours; but when the wind blows and the waves are lifted up in mountain billows, theſe maſſes of ice daſhing againſt one another occaſion ſhocks that make the obſerver tremble. Thunder and lightning ſeldom occur in Greenland, but the Aurora Borealis has frequent and brilliant appearances. At the time of new and full moon, the tide riſes and falls upon this coaſt about three fathoms, and the ſprings and fountains on ſhore riſe and fall with the flux and reflux of the ocean.

The ſoil of Greenland reſembles that of other mountainous countries, the hills being barren, and the vallies and low grounds, eſpecially near the ſea, rich and fruitful. It is, for the moſt part, unfertile clay or ſand. But whatever is ſaid of the fertility of Greenland is applicable only to that part which lies between the 60th and 65th degrees of latitude. The moſt northern parts are totally deſtitute of herbs and plants. This country is ſaid to have formerly produced a great number of cattle, and to have exported conſiderable quantities of butter and cheeſe to Norway. Some parts of the country yielded excellent wheat, and the oaks that grew in it were ſo large as to furniſh acorns as big as apples. In its preſent ſtate, however, though ſome oaks remain, and the traces of ploughed land are perceivable, Greenland is deſtitute both of corn and cattle; but its paſture is good, and if the ſoil were properly cultivated, it would probably yield grain. It produces excellent turnips and coleworts. The ſides of the mountains near the bays are clothed with wild thyme, of powerful fragrance. The country abounds alſo with many other plants, and among its fruits we may reckon juniper-berries, blueberries, bilberries, and bramble-berries.

The animals which are moſt abundant, are rein-deer, dogs reſembling wolves, (ſee DOG,) arctic foxes, and white or polar bears. Hares of different colours are common, but they are ſmaller than thoſe of Denmark and Norway. The walrus, and five kinds of ſeals, frequent the ſhores. Here are found alſo ravens in great numbers, eagles of a very large ſize, falcons, and other birds of prey, and likewiſe a linnet, which warbles very melodiouſly. Whales, ſword-fiſh, porpoiſes, &c., abound on the coaſts; and alſo halybut, turbot, cod, haddock, &c. The ſpecies of inſects exceed 90. The more dubious animals, which are ſaid to inhabit theſe ſeas, are the mermaids, ſea-ſerpents, and krakens. The polar bears, ſeals, and manati, ſays Pennant, (Arctic Zoology,) were originally natives of theſe countries. The other quadrupeds found their way here from either Hudſon's bay or Labrador, on the iſlands of ice. The arctic fox found the ſame kind of conveyance from Greenland to Iceland as it did with the rein-deer to Spitzbergen. To the laſt was wafted, probably from Labrador, the common weaſel, the red or common fox, and the mouſe, which miſſed Greenland, but ſtocked Iceland; and the common bat, which was originally tempeſt driven to the latter from Norway; the wolverene and varying hare never reached farther than Greenland. This, ſays Pennant, ſeems the progreſs of quadrupeds in the frigid zone, as high as land is found.

Greenland is thought to contain many mines of metal. To the ſouthward of the Daniſh colony are ſome appearances of a mine of copper; Mr. Egede once received a lump of ore from one of the natives, and here he found calamine of a yellow colour. Crantz obſerves, that the higheſt mountains of this country are on the weſt ſide, and the rocks are full of clefts, commonly perpendicular, and ſeldom wider than half a yard, filled with ſpar, quartz, talc, and garnets. The rocks are generally rather vertical or ſomewhat inclined, conſiſting of granite, with ſome ſand-ſtone and lapis olaris. Crantz alſo mentions micaceous ſchiſtus, coarſe marble, and ſerpentine; with aſbeſtos and amianthus, cryſtals, and black ſchorl. It is ſaid that fluate of argill, a new ſubſtance, has been recently found in Greenland; and this is perhaps the ſoft tranſparent ſtone of Crantz. The lapis olaris is of ſingular utility in Greenland, and the north of America, as it is uſed for lamps and culinary utenſils.

The preſent inhabitants of the weſtern coaſt of Greenland, and who are the deſcendants of the ancient Skrællings, whom we have already mentioned, and who exterminated the Iceland colony, very much reſemble the American Samoieds and Laplanders in their perſons, complexions, and way of life. They are without doubt a branch of the Eſquimaux of Labrador, who fled that country, and peopled Greenland. They are ſhort, brawny, and inclined to corpulency; with broad faces, flat noſes, thick lips, black hair and eyes, and a yellowiſh tawny complexion. They are for the moſt part vigorous and healthy, but very ſhort-lived, few reaching the grand climacteric, and many dying in their infancy, and in the prime of their youth. The ſharpneſs of the wind, and the glare of the ſnow, render them ſubject to a diſorder of the eyes. They are alſo afflicted with the leproſy; and thoſe who inhabit the northern parts are miſerably tormented with dyſenteries, rheums and pulmonary diſorders, boils, and epilepſy. The ſmall-pox in 1734 made dreadful havock among theſe people, who have no aid from medicine, and who depend merely on their "Angekoks," or conjurers. The Greenlanders, with regard to their conſtitutional temperament and diſpoſition, are cold, phlegmatic, indolent, and dull of apprehenſion; but quiet, orderly, and good-humoured. They live peaceably together; and have every thing in common, without ſtrife and animoſity; and to ſtrangers they are civil and hoſpitable. They never waſh themſelves with water, but lick their paws like the cat, and then rub their faces with them. They eat after their dogs without waſhing their diſhes; devour the lice which devour them; and even lick the ſweat, which they ſcrape off from their faces with their knives. The women waſh themſelves with their own urine, under a notion that it makes their hair to grow; and in the winter-time immediately expoſe themſelves to the air, that the liquor may freeze upon their ſkin.

In their general habit and manner they are intolerably filthy. In times of ſcarcity they ſubſiſt on pieces of old ſkin, reeds, ſea-weed, and a root called "tugloronet," dreſſed with train oil and fat. The dung of rein-deer taken from the inteſtines, the entrails of partridges, and all ſorts of offals, are counted dainties among theſe ſavages; and of the ſcrapings of ſeal-ſkins they make delicate pancakes. The Daniſh proviſions were at firſt taſted by them with diſguſt and abhorrence; but they are now become fond of bread and butter, though they ſtill retain an averſion to tobacco and ſpirituous liquors. The Greenlanders in common content themſelves with one wife, who is condemned to drudgery, and liable to be divorced at the pleaſure of the huſband. Perſons of ſuperior rank and qualities are, however, indulged with a plurality of wives. Their young women are generally chaſte and baſhful; nevertheleſs, at ſome of their feaſts the men retire with the wives of their neighbours for licentious amours. Their ſuperſtitious cuſtoms are innumerable; *e.g.* when a woman is in labour, the goſſips hold a chamber-pot over her head, as a charm to haſten the delivery; and when a child is a year old, the mother licks and ſlabbers it all over, to render it, as ſhe imagines, more ſtrong and hardy. Their cloaths are made of the ſkins of rein-deer, ſeals, and birds. The men wear their hair ſhort, commonly hanging down from the crown of their head on every ſide, and ſquared off at their foreheads. Some cut it off as high as their poll. But it would be a reproach to a woman to cut off her hair, which is never done except in caſes of the deepeſt mourning, or if they reſolve never to marry. All the Greenlanders ſpeak the ſame language, though different dialects prevail in different parts of the country. Some few words are probably the relics of the old Norwegian; but theſe excepted, their language ſeems to have no affinity in etymology, declenſion, or ſignification, with any of the Northern, Tartarian, or Indian languages, as far as they are known to us; but we muſt except the language of the Eſquimaux in Labrador, who ſeem, as we have already ſaid, to be one people with the Greenlanders. Their great number of polyſyllables, and of repeatedly combined words, make their language very intricate. Nevertheleſs, it abounds ſo much with words, that the Greenlanders, like the Chineſe Tartars, have a proper word for every object or art that requires the leaſt diſtinction. Beſides, their words are varied and declined with ſuch different modifications, yet according to a fixed rule with few exceptions, and are attended with prefixes and ſuffixes, far more than the Hebrew, that the language is not only graceful, but plain and unequivocal. Moreover, they join many words together, as we have already ſaid, like the North Americans, ſo that they can expreſs themſelves very conciſely and yet ſignificantly. Some of our letters are wanting in their language, and they never begin a word with B, D, F, G, L, R, or Z. They ſeldom join many conſonants together, and never at the beginning of a ſyllable. The accent, upon which much depends, muſt be laid upon the proper ſyllable, commonly the laſt; and the Greenlanders, eſpecially the women, accompany many words, not only with a particular accent, but with a certain ſignificant aſpect, which is neceſſary to be regarded in order to aſcertain their meaning. They have but few adjectives, and theſe are moſtly participles; they are placed after the ſubſtantive, which always begins the ſentence. Subſtantives, as well as verbs, have ſingular, dual, and plural numbers, but no genders, and they want no article. The dual and plural are formed according to the different termination of the word, with few exceptions. The declenſions are eaſy; the genitive has at the end a *b*, or if a vowel follows, an *m*, either by addition or change; and the reſt of the caſes have a prepoſition affixed to them. The pronouns are not placed before the word, but one or two of its letters are attached to it at the end, and in different ways according to the different numbers. They have only five prepoſitions, which are not ſet before the nouns, as in other languages, but at the end, and again are varied in declining. The verbs have been divided into five conjugations, according to their terminations. They have three tenſes, the preſent, preterperfect, and future; and they have ſix moods, the indicative, imperative, permiſſive, conjunctive, and infinitive. The Greenlanders have no verbs deponent nor paſſive, but the latter are formed from the active by ſome adjunction. They have ſeveral claſſes of adverbs, like other nations; but their numerals are few, ſo that they can ſcarcely count five; but in order to arrive at 20, they count the fingers of both hands and the toes of both feet. If they want to proceed farther, they begin again with their fingers and toes. They tack their conjunctions to the end of a word, as the Latins do their *que*; and they do not want interjections. Their ſyntax is ſimple and natural; the capital word ſtands in the front, and the reſt follow in order according to their importance. Their ſtyle or mode of ſpeaking is not at all hyperbolical, pompous, or bombaſt, like that of the orientals, but ſimple and natural; yet they are fond of ſimilitudes and metaphors. Their poetry has neither rhyme nor meaſure; but it conſiſts of ſhort periods; which, however, are ſung to a certain time and cadence.

The Greenlanders have no traditions of the moſt memorable events of their anceſtors in heroic ſongs, as other nations have, who poſſeſs no written records. All they can ſay of their progenitors is, that they were brave ſeal-catchers, and that they killed the old Norwegians. Yet in their ſatirical ſongs, to which they are much addicted, they are more acute. They are well verſed in genealogy, and can often trace their pedigree as far back as ten of their progenitors, together with all the collateral branches. Their imperfect arithmetic we have already noticed. Of writing they have no conception. On their firſt acquaintance with Europeans, they were frightened by ſpeaking paper. In chronology, they reckon their years by winters, and their days by nights. They are not learned enough to fix the equinoxes, but they can gueſs at the winter ſolſtice, within a few days by the ſun-beams upon the rocks; and then they celebrate their new year by a ſun-feaſt. From hence they reckon three full moons to the ſpring, and then they move from their winter houſes into tents. In the fourth moon, *i. e.* in April, they know that the ſmall birds make their appearance, and the ravens lay eggs. In the fifth their angmarſet, and the ſeals with their young ones give joy to their coaſts by their revolutionary viſit. In the ſixth the eider-fowls breed. When they loſe the moon in the bright ſummer nights, they carry on their calendar partly by the growth of eider-fowls, and ſize and ſhape of the ſeals, and partly by the ſhining of the ſun on the dial of the rocks and mountains; ſo that they exactly tell when the ſeals, fiſhes, and birds will arrive in flocks and ſhoals here and there, and when it is time to repair to the winter-houſes, in which they generally ſhelter themſelves ſoon after Michaelmas. They divide the day according to the ebb and flood, and the night by the riſing and ſetting of certain ſtars. They think the globe of the earth ſtands upon poſts, which are ſo rotten with age, that they often crack; and that they would have ſunk long ago, if they had not been kept in conſtant repair by the Angekoks, who ſometimes bring back a piece of rotten wood as an evidence of their important ſervice. Their aſtronomy makes the firmament to reſt on a lofty pointed hill in the north, and on that centre it performs its revolutions. But this ſpecimen is ſufficient. When it thunders, two women are ſtretching and flapping a dried ſeal-ſkin, and the thunder is occaſioned by that rattle. The myſtery of the Aurora Borealis is unravelled by the ſouls of the dead friſking at a dance or a foot-ball. The rains are the overflowings of the celeſtial reſervoirs; and if the banks ſhould break, the ſky would fall down. Such is their meteorology! In medicine and ſurgery they are no leſs ignorant than in the other ſciences.

When a Greenlander is in the conflicts of death, they array him in his beſt cloaths and boots, and bend his legs up to his hips, probably that his grave may be the ſhorter. After death, they ſilently bewail him for a ſhort hour, and next prepare for his burial. The corpſe, being wrapped and ſewed up in the man's beſt ſeal or deer-ſkin, is laid in the burying place, covered with a ſkin, and alſo with ſome green ſods, and finally with heaps of great broad ſtones to keep off the birds and foxes. Near the burying ſpot they depoſit the kajak and darts of the departed, and the tools he daily uſed; or if the deceaſed was a woman, her knife and ſewing implements, that they might not be defiled by them, or ſorrow too much on their account, or becauſe they ſhould want them in another world. After the interment, thoſe who attended the proceſſion, betake themſelves to the houſe of mourning: then the men ſit ſilent for ſome time with their elbows leaning upon their knees, and their heads between their hands; while the women lie proſtrate upon their faces on the ground, and ſoftly weep and ſob. Then the neareſt relation pronounces an eulogy, reciting the good qualities of the deceaſed, and at every period deploring his loſs with loud crying and weeping. After this mournful ditty, the women continue their lamentations in a tremendous howl. This kind of mourning is continued for a week or a fortnight. The howling is after intervals renewed, and prolonged for ſome weeks, and in ſome caſes for a whole year.

As for the religion, or rather the ſuperſtition of the ancient Greenlanders, they are reported to be ſuch groſs idolaters as to worſhip the ſun, and ſacrifice to the devil, that he might forward, or at leaſt not hinder, their hunting and fiſhing. The firſt miſſionaries, however, conceived that the Greenlanders had no kind of religion or idolatrous worſhip; and that there was not any obſervable trace of their entertaining any conception of a Divine Being. Others, however, have thought, with greater reaſon, that a faint idea of the Divine Being lay concealed in the minds of theſe people, becauſe they directly aſſented without any objection to the doctrine of God and his attributes. Among the Greenlanders, different opinions are entertained concerning the ſoul of man; ſome ſuppoſing that it is material or corporeal, and others that it is a ſpiritual eſſence, different from the body, and all material ſubſtances, and capable of ſurviving after death. They ſeem to have ſome confuſed and indiſtinct notions of a future ſtate; of the place which is to be the final abode of good men; and of the nature of their reward. The moſt ſtupid Greenlanders, it is ſaid, conceive a horror at the thoughts of the entire annihilation of the ſoul. They place their hell in the ſubterraneous regions, which are devoid of light and heat, and filled with perpetual terror and anxiety. The Greenlanders ſpeak of other ſuperior and inferior ſpirits, beſides the ſoul of man, which bear ſome reſemblance to the major and minor gods of the ancient heathens. Of the firſt rank there are only two; a good ſpirit and a bad one. Beſides the great ſpirits to an audience with whom an Angekok only can be admitted, there are other leſſer ſpirits in all the elements.

The Greenlanders believe in apparitions, of the ghoſts of the deceaſed. The “Angekoks” are their ſorcerers or diviners, to whom peculiar privileges and honours belong. Although the Greenlanders have neither religion nor government, they are free from many of the groſſer vices, which may be found among perſons much more enlightened than themſelves.

The traffic of the Greenlanders is very ſimple and conciſe, and is carried on altogether by barter. They very rarely cheat, or take the advantage of one another, much leſs ſteal, which they reckon infamous; but they glory in over-reaching, or robbing an European, becauſe they think it is a proof of their ſuperior wit and ingenuity. Their traffic is carried on partly among themſelves, and partly with factors and ſeamen. Wherever there is a great aſſembly, or rendezvous of Greenlanders, as at a dancing match, or the ſun-feaſt in winter, there are always ſome that expoſe their wares to view, and announce publicly what goods they want in exchange. As thoſe in the ſouth have no whales, and thoſe in the north no wood, many boats of the Greenlanders coaſt every ſummer out of the ſouth, and even from the eaſt ſide of the land, and proceed from two to four hundred leagues, as far as Diſko, with their kajaks and women's boats, and the tackle and implements belonging to them, and barter wood for the horns of the unicorn fiſh, teeth, bones, whalebones, and whale's ſinews, and part of theſe they truck on their return home. In theſe voyages they take with them their whole family and ſubſtance; and ſometimes form a new ſettlement in the courſe of their voyage. The Greenlanders vend their fox and ſeal-ſkins, and eſpecially their blubber, to agents or factors, and receive in return iron points for their darts, knives, lock-ſaws, gimblets, chiſſels, and ſewing needles; alſo, ſtriped linen and cotton, kerſeys, woollen ſtockings and caps, handkerchiefs, cheſts or boxes, wooden diſhes, pewter plates, copper kettles, looking-glaſſes, combs, ribbons, and all ſorts of toys for children. They are fondeſt of buying ſnuff, alſo guns, powder, and ſhot; tobacco, which they uſe only as ſnuff, ſerves inſtead of ſmall money with them. Indeed, they expect a little tobacco for every ſervice they perform.

The aſſembly for dancing, and the ſun-feaſt above-mentioned, are not religious acts or ceremonies, but mere ſports and amuſements. The ſun-feaſt is kept at the winter ſolſtice, to rejoice at the return of the ſun, and the renewal of good hunting and fiſhing weather. For this purpoſe they aſſemble all over the country in large parties, and treat one another in the beſt manner they are able. When they have gorged themſelves with food, they riſe up to play and to dance. The means of intoxication they do not poſſeſs, and drink only water. Their only muſical inſtrument is the drum, which is beaten to common muſical time. The muſic and dancing are accompanied with a ſong in honour of ſeal-catching, and ſuch kinds of exploits; the performer extols the noble deeds of his anceſtors, and expreſſes his joy at the return of the ſun in the hemiſphere. Every ſtanza of his ode is accompanied by the auditory. The following is a ſpecimen of a complete cantata; the ſecond and fourth lines expreſſing the chorus:

“ The welcome ſun returns again,
Amna ajah, ajah, ah-hu!
And brings us weather fine and fair,
Amna ajah, ajah, ah-hu!”

Such dancing meetings are appointed at other ſeaſons of the year, when they have leiſure to attend them. It is ſomewhat ſingular, and deſerves mention, that they decide their quarrels by ſinging and dancing, and they call this a “Singing Combat.” A Greenlander, who conceives himſelf injured, compoſes a ſatirical poem, and repeats it ſo often with ſinging and dancing, till his domeſtics, and particularly the women, are able to remember it. He then publiſhes a challenge that he will fight a duel with his antagoniſt, not with a ſword but with a ſong.

The reſpondent appears in the appointed place; when the accuſer begins to pronounce his ſatire to the beat of the drum, and his party join with repeating “Amna ajah,” which occaſions laughter among the attendants.

The defendant then retorts in the ſame manner, and the laugh changes ſides; the plaintiff again renews the ſame kind of aſſault. The whole body of attendants conſtitute the jury, and confer the laurel on the victor, and afterwards the two contending parties are the beſt friends.

The Greenlanders are employed through the whole year in fiſhing or hunting. At ſea they purſue whales, morſes, ſeals, fiſh for food, and ſea-fowl. On ſhore they hunt the rein-deer in different parts of the country. And they have methods peculiar to themſelves, and correſponding implements, for accompliſhing their objects both by ſea and land; which we ſhall not here deſcribe. The Greenland canoe, or “kaiak,” like that in Nova Zembla and Hudſon's bay, is about three fathoms in length, pointed at both ends, and ¾ of a yard in breadth. It is conſtructed of thin rafts faſtened together with the ſinews of animals, and covered with dreſſed ſeal-ſkin, both above and below, ſo that only a circular hole is left in the middle, large enough to admit the body of one man. Into this the Greenlander thruſts himſelf up to the waiſt, and faſtens the ſkin ſo tight about him that no water can enter. Thus ſecured, and armed with a paddle broad at both ends, he ventures out to ſea in the moſt ſtormy weather to catch ſeals and ſea-fowl; and if he is overſet, he can eaſily raiſe himſelf by means of his paddle. The “kone-boat” is made of the ſame materials, but more durable; and ſo large, that it will contain 50 perſons with all their tackle, baggage, and proviſions. It is fitted with a maſt, which carries a triangular ſail made of the membranes and entrails of ſeals, and is managed without the help of braces and bowlines. Theſe kones are flat-bottomed, and ſometimes 60 feet in length. They are left to the conduct of the women, who are obliged to do all the drudgery, including even the building and repairing of their houſes, while the men are wholly employed in preparing their hunting implements and fiſhing-tackle.

Greenland is a country very thinly inhabited. In winter they live in houſes and in ſummer in tents. The houſes are conſtructed of ſtones, on a ſteep rock, with layers of earth and ſods between them. On theſe walls they reſt the beam, or connected beams, for the length of the houſe, being from 4 to 12 fathom; and over theſe they lay the rafters, with ſmall wood between them; the whole is covered with bilberry-buſhes, and then with turf, with fine earth on the top. Their houſes have neither door nor chimney; the uſe of both being ſupplied by a vaulted paſſage made of ſtone and earth, entering through the middle of the houſe. The walls are hung on the inſide with old worn tent and boat ſkins, faſtened with nails made of the ribs of ſeals; and the roof is covered with them on the outſide. In theſe huts, ſo conſtructed, they are guarded from wind, damp, and cold. The floor is divided into ſeveral apartments, ſeparated by ſkins, according to the number of families for which it is deſigned. On theſe floors they ſleep on pelts; and they commonly ſit in them all day long, the women cooking and ſewing, and the men carving their tackle and tools. On the front wall of the houſe are ſeveral ſquare windows, about two feet in ſize, made of ſeal's guts and halibut's maws, and ſewed ſo neat and tight, that the wind and ſnow are kept out, and the light let in. Theſe huts are well warmed with fires, and lighted by means of lamps filled with train oil, and furniſhed with moſs inſtead of a wick, which burns ſo bright that the houſe is both lighted and warmed by it. Over the lamp is ſuſpended a baſtard-marble kettle, in which they boil all their meat; and over this again is a wooden rack, on which they lay their wet cloaths and boots to dry. On the outſide of their dwelling-houſe they have their little ſtore-houſes, in which they lay up their little ſtock of fleſh, fiſh, train oil, and dried herrings; and cloſe by their ſtore-houſes they lay their boats, with their bottoms upwards, under which they hang their hunting and fiſhing tackle and their ſkins Their ſummer tents are made with poles, put together in a conical form, covered on the inſide with reindeer ſkins, and on the outſides with ſeal-ſkins, doubled, or ſo dreſſed that the rain cannot penetrate them. Crantz's Hiſtory of Greenland, vol. i.

GREENLAND, *Eaſt*, or *Spitſbergen*, was formerly conſidered as part of the continent of Weſt Greenland, but it is now known to be a collection or group of iſlands, varying in their extent, and lying between 76° 46′ N. lat. the latitude of the South Cape, and 80° 30′, the northernmoſt point of the Seven iſlands, and between 9° and 23° E. long. Sir Hugh Willoughby, who firſt diſcovered land in this high northern latitude, A. D. 1553, called it *Groenland;* conceiving it to be part of the weſtern continent. It was afterwards viſited, A. D. 1595, by William Barentz and John Cornelius, two Dutchmen, who claimed the honour of the firſt diſcovery, and called the country “Spitſbergen,” or ſharp mountains from the numerous ſharp pointed and rocky mountains which they obſerved in it; and in order to aſcertain their own claims, they pretended that this was not the country diſcovered by ſir Hugh Willoughby, which in the maps and charts delineated by the Hollanders was denominated “Willoughby land,” though no ſuch land ever exiſted. It is moreover ſaid, that before the voyage of theſe Dutchmen, an Engliſh navigator, whoſe name was Stephen Burrows, had coaſted along a deſolate country from 78° to 80° 11′ N. lat. which muſt have been Spitſbergen. This country was alſo viſited at different times by navigators, who were employed in exploring a paſſage to the Eaſt Indies by the north-pole; a project which was ſuggeſted and ſtrongly recommended by Robert Thorne, a merchant of Briſtol, as early as the year 1527. Bourne, in his “Regiment of the Sea,” written about the year 1577, mentions this as one of the five ways to Cathay, and ſeems to admit the practicability of it from a miſtaken notion of the mildneſs of the climate near the pole, owing to the conſtant preſence of the ſun during the ſummer. In 1607, a voyage was propoſed by ſome London merchants, for the diſcovery of a paſſage by the north pole to Japan and China, and it was undertaken by Henry Hudſon, who fell in with land to the weſtward in 73° N. lat.; and ſoon after he fell in with Spitſbergen, where he met with much ice; and this navigator advanced to the latitude of 80° 23′; but he was prevented from proceeding farther by the ice. In 1609, Jonas Poole was appointed by the Muſcovy company on the ſame ſervice; and he with much difficulty made the ſouth part of Spitſbergen, afterwards ſailing along and ſounding the coaſt, giving names to ſeveral places, and making many very accurate obſervations. Having twice attempted in vain to get beyond 79° 50′, he was obliged to relinquiſh his object and to return home. A ſecond attempt in the following year was equally unſucceſsful. In the year 1614, another voyage was undertaken, in which Baffin and Fotherby were employed; and Fotherby made a ſecond attempt in the following year; but their progreſs was obſtructed by the ice. This country and the adjoining ſeas have ſince been frequently reſorted to by ſhips employed in the whale fiſhery; but its ſituation was never accurately aſcertained till captain Phipps (now lord Mulgrave) undertook a voyage by order of his majeſty George III. in the year 1773. He found that the land, which was formerly ſuppoſed to extend as far as 82° N. lat., terminated with the “Seven iſlands,” the moſt northerly point of which does not exceed 80° 30′ N. lat. He obſerved other lands lying eaſtward at a conſiderable diſtance; but Spitſbergen was found to be encompaſſed by water and in no part of it to be contiguous to the continent of Aſia. He explored, with a degree of reſolution and perſeverance that did honour to himſelf and his aſſociates in this expedition, the northern and weſtern coaſts, though he was prevented by the ice from advancing ſo far northwards as he wiſhed; and he aſcertained by accurate obſervation the longitudes and latitudes of ſeveral points, capes, and bays, which he viſited. On his approach to the land he picked up a piece of drift wood, which was found to be fir, and not worm-eaten; and upon ſtanding cloſe in with the land, the coaſt appeared to be neither habitable nor acceſſible; it was formed by high, barren, black rocks, without the leaſt marks of vegetation; in many places bare and pointed, in other parts covered with ſnow, appearing even above the clouds; the vallies between the high hills were filled with ſnow or ice. "This proſpect," he ſays, in his "Journal," printed in 1774, "would have ſuggeſted the idea of perpetual winter, had not the mildneſs of the weather, the ſmooth water, bright ſun-ſhine, and conſtant day-light, given a chearfulneſs and novelty to the whole of this ſtriking and romantic ſcene." The current on this coaſt was found, both by the common and Bouguer's log, to run north half a knot an hour. The height of one mountain, above the level of the ſea, was found by meaſurement with the megameter, to be 15,035 feet, but by M. de Luc's calculation from obſervations with the barometer it was found to be 1588½.

Among the harbours in which captain Phipps anchored, we may mention a ſmall bay to the ſouthward of Magdalena Hook and Hamburgher's bay; the former in N. lat. 79° 34′, the ſame as Fotherby obſerved it to be in 1614: the high-water in this bay full and change at half an hour paſt one, or with a S.S.W. moon, which agrees exactly with Baffin's obſervation in 1613, the flood coming from the ſouthward. Another anchoring place was Vogel Sang, N. lat. 79° 50′. E. long. 10° 2′ 30″; the north eaſternmoſt point being the Cloven cliff, 79° 53′. E. long. 9° 59′ 30″, a bare rock ſo called from the reſemblance of its top to a cloven hoof, which appearance it has always exhibited, having been ſo named by ſome of the firſt Dutch navigators who frequented theſe ſeas. It is alſo nearly perpendicular, ſo that it is never diſguiſed by ſnow, and on theſe accounts it is one of the moſt remarkable points on the coaſt. The ſouthernmoſt land is an high bluff point, called by the Dutch Vogel Sang. This ſound, though open to the northward, is not liable to any inconvenience from that circumſtance, the main body of ice lying ſo near as to prevent any great ſea; nor are ſhips in any danger from the looſe ice ſetting in, as this road communicates with ſeveral others formed by different iſlands, between all which there are ſafe paſſages. To all the ſounds and harbours formed by this knot of iſlands the old Engliſh navigators had given the general name of Fair Haven, of which Fotherby took a *plat* in 1614. In this ſituation Hackluyt's Head-land was found to be in N. lat. 79° 47′. E. long. 9° 11′ 30″. The tide roſe about four feet, and flowed at half an hour after one, full and change. The harbour of Smeerenberg, diſtant about 11 miles, N. lat. 79° 44′. E. long 9° 50′ 45″, has good anchorage in 13 fathom, ſandy bottom, not far from the ſhore; and it is well ſheltered from all winds. The iſland cloſe to the place where our navigators lay is called Amſterdam iſland, the weſternmoſt point of which is Hackluyt's Head-land; here the Dutch formerly uſed to boil their whale-oil, and the remains of ſome conveniences erected by them for that purpoſe are ſtill viſible. They once attempted to make an eſtabliſhment, and left ſome people to winter here, who all periſhed. Nevertheleſs, as they ſeem to have died not through the intenſity of the cold, but in conſequence of being attacked by the ſcurvy, and as others, both Engliſh and Ruſſian ſailors, have wintered here, a colony might be ſettled in this country, if ſuch an eſtabliſhment were likely to anſwer any good purpoſe. The Dutch ſhips ſtill reſort to this place for the latter ſeaſon of the whale fiſhery. The ſtone found in this country was chiefly a kind of marble, which diſſolved eaſily in the marine acid. But our navigators perceived no marks of minerals of any kind, nor the leaſt appearance of preſent, or remains of former volcanos. Neither did they meet with inſects or any ſpecies of reptiles; not even the common earthworm. They ſaw no ſprings, or rivers; the water, which was found in great plenty, being altogether produced by the melting of the ſnow from the mountains. During their ſtay in theſe latitudes, they had no thunder or lightning. The ſky was in general loaded with hard white clouds; ſo that neither the ſun nor the horizon was wholly free from them even in the cleareſt weather. They could always perceive when they approached the ice, long before they ſaw it, by a light appearance near the horizon, which the pilots called the "blink of the ice." (See BLINK.) One of the moſt remarkable phenomena which this country exhibited was the "iceberg." (See ICEBERG.) Of the animals and plants of Spitzbergen, captain Phipps has given an account in the appendix to his Journal. The animals are the arctic walrus, the common ſeal, the arctic fox, the polar bear, the rein-deer, the common whale, the fin fiſh; and the birds the eider-duck, the puffin, the alca alle, the fulmar, the colymbus grylle and troile, the northern diver, the larus riſſa, arctic gull, and larus eburneus, the greater tern, the greater brambling, the ſea-ſnail, the coal-fiſh, the prawn, the cancer-boreas, or ſingular ſpecies of crab, and cancer nujax, not before deſcribed, and alſo cancer ampulla, and cancer pulex; ſeveral ſpecies of vermes, and ſhell-fiſh. Among the plants are a ſmall ſpecies of agroſtis, ſeveral ſpecies of ſaxifraga, of bryum, of cochlearia, and of lichen.

GREENLAND, a town of America, in Rockingham county, New Hampſhire, near the ſea, five miles ſoutherly from Portſmouth, incorporated in 1713, and containing 548 inhabitants.

GREENLAND *Fiſhery*. See *Whale* FISHERY.

GREENLAND *Company*. A joint ſtock of 40,000*l*. was by ſtatute to be raiſed by ſubſcribers, who were incorporated for fourteen years from the firſt of October 1693, and the company to uſe the trade of catching whales, &c. into and from Greenland, and the Greenland ſeas; they may make bye-laws for government, and of the perſons employed in their ſhips, &c. (Stat. 4 and 5 W. III. cap. 17.) This company was farther encouraged by parliament in 1696; but partly by unſkilful management, and partly by real loſſes, it was under a neceſſity of entirely breaking up, before the expiration of the term aſſigned to it, ending in 1707. But any perſon who will adventure to Greenland for whale-fiſhing, ſhall have all privileges granted to the Greenland company, by 1 Anne, cap. 16. and thus the trade was again laid open. Any ſubjects may import whale-fins, oil, &c. of fiſh caught in the Greenland ſeas, without paying any cuſtoms, &c. ſtat. 10 Geo. I. cap. 16. And ſhips employed in the Greenland fiſhery are to be of ſuch burden, provided with boats, ſo many men, fiſhing-lines, harping-irons, &c. and be licenſed to proceed; and on their return ſhall be paid 20*s*. per ton bounty, for whale-fins, &c. imported. 6 Geo. II. cap. 33. See *Whale*-FISHERY.

GREENLAW, in *Geography*, a town of Scotland, which, though the county-town of Berwickſhire, is an inconſiderable place, pleaſantly ſituated in a plain, bathed by the Blackader or Blackadder. The acclivities of the neighbouring eminences are tolerably cultivated. In its vicinity, about midway between Greenlaw and Kelſo, on a riſing ground, is Herne caſtle, which commands a view of the greateſt part of the Merſe and Roxburghſhire, and was celebrated during the contentions on the border. It was a noted place of defence, often beſieged by the Engliſh, and demoliſhed by Cromwell. It is diſtant 37 miles S.E. from Edinburgh, and contains 1270 inhabitants.

GREENOCK, the principal ſea-port town on the firth of Clyde, ſituated on the ſouth bank of the river, about 24 miles below the city of Glaſgow. The town of Greenock is pretty well ſituated for commercial purpoſes, but in other reſpects it is neither pleaſant nor ſo circumſtanced as to afford the proſpect of any great increaſe either of extent or population. Indeed the great number of young men, who, from habits of imitation as in other ſea port towns, early attach themſelves to a ſeafaring life, muſt preſent of itſelf a great obſtacle to the latter. The town of Greenock is held under and is entirely ſurrounded by the lands of ſir John Stewart of Blackhall, bart., who is feudal ſuperior, and no purchaſe or acquiſition of ground, either for the purpoſes of extenſion or improvement, can be had from any other perſon. This muſt of itſelf render extenſion a matter of more difficulty than where there are many landed proprietors, the lands of ſome of whom, from the common caſualties and viciſſitudes of human affairs, muſt be occaſionally in the market.

The harbour of Greenock is divided into two compartments, and is entirely ſurrounded by well-built and commodious quays of freeſtone. The entrance is narrow, and in the centre oppoſite to the end of the mid quay, which ſerves as the diviſion of the harbours. The eaſtern harbour is ſhallow, and is therefore moſtly frequented by coaſting veſſels, herring buſſes, fiſhing boats, and other ſmall craft. The weſt harbour, being conſiderably deeper, is the general reſort of Weſt Indiamen, American traders, and other veſſels of greater burthen. In the weſt harbour is a very capital dry or graving dock, with flood gates to exclude the water, and capable of containing two large ſhips at the ſame time. It has been long in contemplation to improve the harbour of Greenock by the erection of wet docks, ſimilar to thoſe of London, Liverpool, Hull, and Leith, but probably from the difficulty of engaging the joint conſent of the numerous intereſts concerned, and other cauſes, no ſteps have been hitherto taken for carrying this ſcheme into effect. The principal deficiency of the harbour of Greenock, excluſive of the ſhips bottoms taking the ground every ebb tide, ariſes from want of water, there being never more than ſeventeen or eighteen feet in the harbour, even at ſpring tides. Hence large veſſels are obliged to diſcharge part of their cargoes into lighters in the roads before they can come into the harbour at all. This is of leſs conſequence where the cargo is to be brought to Glaſgow, if the weather be mild, but it is very inconvenient and expenſive when the cargo is to be landed, and when the weather is boiſterous. The whole riſe of the tide at Greenock is only about twelve feet, whereas at Liverpool it is thirty-ſix and at Briſtol forty-two. This alſo forms an additional diſadvantage to the harbour of Greenock, and preſents a very great obſtacle to every plan of artificial improvement. With all theſe diſadvantages, however, it has many advantages over the neighbouring harbour of port Glaſgow, ſituated about three miles farther up the river. The chief obſtacle to veſſels of great burthen making any of theſe ports, is an immenſe bank of ſand, accumulated for many ages in this *embouchure* of the Clyde by the current of the river, and which is ſenſibly though ſlowly increaſing. Indeed nearly oppoſite to port Glaſgow, this bank is entirely uncovered for miles at low water. Notwithſtanding theſe natural diſadvantages, the favourable ſituation of the Clyde for maritime intercourſe with every part of the weſtern hemiſphere and the ſouth of Europe, the great coaſting trade with the weſtern parts of England and Wales, and with Ireland, and the extenſive herring fiſhery, has raiſed Greenock to a high rank among the commercial ports of Britain, and has been productive of the acquiſition of ſplendid fortunes to many of the principal inhabitants. As Greenock is not the ſeat of any ſtaple manufactory, this carrying trade is her chief, and indeed may be fairly called her only ſupport. During the American war, when the carrying trade was entirely ſuſpended in ſome channels, and greatly impeded in all the others, a number of ſhip-owners fitted out their veſſels as privateers, but in general theſe ſpeculations were not productive of gain to the adventurers, and in ſome inſtances with ſerious loſs. In the recent wars no attempts at privateering have been made.

The town of Greenock is governed by two magiſtrates, elected annually, and a council; beſides whom, the baron baillie, nominated by the ſuperior, alſo poſſeſſes a juriſdiction. The ſheriff court of the county of Renfrew is held at Paiſley, to which the inhabitants of Greenock are amenable, the ſame as the reſt of the county.

In the external appearance of Greenock there is little elegance or ſplendour to be ſeen. In the centre of the town there is a ſmall ſquare, immediately fronting the mid-quay, which divides the harbour. In this ſquare is a very handſome church of modern architecture. The other buildings are the inns, of which the chief, recently built upon a tontine ſcheme, like that of Glaſgow, is a very ſpacious, and even ſplendid houſe. There is alſo a ſmall neat theatre, the private property of Mr. Stephen Kemble, the manager, and ſome dancing-halls for the occaſional recreation of the inhabitants and ſtrangers, of whom, from the maritime ſituation, there is, at certain ſeaſons, particularly at the arrivals of the Weſt India fleets, a conſiderable influx.

The ſcenery of the Clyde around Greenock is pictureſque and ſublime. The river is about ſeven miles broad to the oppoſite ſhore, where the village of Helenſburg is erected upon the property of ſir James Colquhoun of Luſs, bart. This village is built in a very pleaſant ſituation, upon a fine bay, formed by two projecting promontories, *viz.* by the hill of Ardmore, on the eaſt, and by Roſeneath, the property, and one of the ſplendid reſidences of the duke of Argyle, on the weſt. Beyond this, to the weſtward, appear the lowering mountains of Argyleſhire, between which is the vaſt arm of the ſea, Lochlong, which is twenty-four miles in length, and in ſome places ſaid to be unfathomably deep. About two miles to the weſt is a ſmall village, called Gourock, ſituated on a very fine deep bay, well ſheltered by projecting head-lands, with a very good bottom for anchorage. It is the opinion of moſt profeſſional men, whether engineers or ſeamen, that this ſituation affords by far the greateſt number of natural advantages for a large and commodious ſea-port upon the Clyde; and it is almoſt ſingular that Greenock ſhould have riſen to its preſent commercial importance, whilſt Gourock, ſituated within leſs than two miles, and poſſeſſing every ſuperiority of phyſical advantage, ſhould have remained an inſignificant village. However this may have originated, too much capital has now been expended upon Greenock and Port Glaſgow, to leave the ſmalleſt room to ſuppoſe that they will be in any reſpect rivalled by a village which poſſeſſes nothing but natural ſituation to recommend it. On the road from Greenock to Gourock are many very fine villas, belonging to the opulent merchants of Greenock. At both Greenock and Gourock are extenſive rope-works, belonging to the ſame company of proprietors. A little below Gourock is the Clough light-houſe, a very high and well-built tower, lighted by reflectors, for the ſafety of veſſels coming up, or going down the channel during the night. Some miles below this is the iſland of Bute, belonging chiefly to the nobleman to whom it gives the title of marquis. Bute is about ſeven miles long, and generally level and fertile. Mount-ſtewart-caſtle, the reſidence of the noble proprietor, is ſituated near the middle of the iſland, on the ſouth ſide, and is a ſuperb and delightful place. Of the other proprietors, lord Bannatine, one of the Scottiſh judges, is the moſt conſpicuous. The chief, and, indeed, almoſt only town on the iſland, is Rothſay, from which his royal highneſs the prince of Wales derives one of his Scottiſh titles, is a handſome, clean, ſmall town, and has a conſiderable cotton mill and manufactory by it, belonging to a company of manufacturers in Glaſgow. There are alſo the ruins of an old caſtle, which appears to have been of great extent, and once belonged to the royal family of Scotland. The inhabitants of Rothſay are chiefly ſea-faring people, and employ themſelves much in the herring fiſhery during the ſeaſon. Large quantities of fine cod-fiſh are alſo caught off the coaſts of Bute, Arran, and Argyleſhire, with which the markets of the weſt of Scotland are ſupplied, generally at a rate not exceeding two-pence *per* pound of 22½ ounces. Contiguous to Bute is a ſmall iſland, called Inch Marnock, which is level and cultivated. It is the reſidence only of thoſe employed in its cultivation. The iſland of Arran is nearly thirty miles in length, and is very mountainous. The higheſt hill, called Goatfield, is ſeen from a great diſtance. The iſland of Arran is the property of the duke of Hamilton, who is earl of Arran, who has a fine houſe, called Brodick caſtle, on the iſland, where his family ſometimes reſide, eſpecially during the ſeaſon for ſhooting grouſe or black game. Arran uſed to be much noted for a ſmuggling trade, both in contraband articles brought by the ſeamen employed in the veſſels trading to the Clyde, and alſo in the diſtillation of whiſky. The vigilance of the revenue cruiſers in the Clyde has, in a great meaſure, checked the former, and that of the exciſe officers the latter. On Arran are found a number of fine ſtones, and it is ſometimes viſited by lapidaries, during the ſummer, for the purpoſe of ſearching for them, or of purchaſing thoſe occaſionally picked up by the natives. On the iſland are only two ſmall towns or villages, *viz.* Brodick and Lamlaſh, the latter of which, being defended from the ſouth winds by an iſland in the mouth of the bay, is reſorted to as a ſhelter in ſtormy weather by the ſhips and veſſels navigating the frith of Clyde.

Beſides thoſe already mentioned, there are a few ſmaller iſlands in the frith, *viz.* the Cumbraes, which are two ſmall iſlands lying pretty cloſe to the ſouthern ſhore, near the Renfrewſhire coaſt, oppoſite to the village of Largs, about 16 miles below Greenock. The larger iſland is about two miles long, and on it is a very neat village, called Milport, chiefly inhabited by fiſhermen and ſeamen's families. The leſſer iſland is a mere rock, where a few perſons reſide, who take charge of the light-houſe, and ſometimes perſons in a ſtate of inſanity are boarded here by their relatives, on account of the purity of the air, and the retirement of the ſituation. Farther down, and near the Ayrſhire coaſt, is the ſtupendous rock, or crag of Ailſa, from which the proprietor, the earl of Caſſius, derives his Britiſh title. Ailſa is a high abrupt and barren rock, totally uninhabited, and covered by myriads of ſea-fowl, in ſearch of which it is ſometimes viſited. Of the general trade of the Clyde notice has already been taken under the article Glasgow.

GREENORE Point, a cape of Ireland, in the county of Wexford, in the Iriſh ſea. N. lat. 52° 16′. W. long. 6° 18′ from Greenwich.

GREENSBORO, a poſt-town of America, in Weſt Cheſter county, New York; 264 miles from Waſhington.

GREENSBOROUGH, a poſt-town and chief town of Greene county in Georgia, 30 miles from Lexington: containing 25 houſes, a court-houſe, gaol, and Preſbyterian meeting-houſe. Lands are appropriated for the eſtabliſhment of an academy in this town.—Alſo, a neat townſhip in Orleans county, in Vermont, containing 280 inhabitants.

GREENSBURG, a poſt-town, and capital of Weſtmoreland county, in Pennſylvania, ſituated on a branch of Sewickly creek, which empties into Youghiogany river. It contains 100 dwelling houſes, a German Calviniſt church, a brick court houſe, a ſtone gaol, 270 miles W. by N. from Philadelphia.—Alſo, a poſt-town in Green county, Kentucky; 875 miles W. by S. from Waſhington.

GREENSVILLE, a county of Virginia, encompaſſed by Brunſwick, Southampton, and Suſſex counties, on the N. W. and E. and by N. Carolina on the S. It is about 24 miles long, and 20 broad, and contains 3611 free inhabitants, and 4116 ſlaves.

GREENVILLE, *Sir* Richard, in *Biography*, a gallant naval officer, ſon of ſir Roger, of an ancient family, in the weſt of England, was born about 1540. At the age of fixteen he obtained leave from queen Elizabeth, with others of his young countrymen, to ſerve in the imperial army in Hungary, againſt the Turks. Upon his return, he engaged with the troops employed for the reduction of Ireland, where he diſplayed ſo much courage and prudence, as to obtain the appointment of ſheriff of the city of Cork. He ſat in parliament in 1571, as knight of the ſhire for the county of Cornwall. He was afterwards high ſheriff of the county, and received the honour of knighthood. Notwithſtanding his civil employments, his attention was chiefly fixed upon plans of foreign diſcovery and ſettlement, propoſed by his relation ſir Walter Raleigh. When the patents were made out for the purpoſe, ſir Richard obtained the command of a ſquadron fitted out for the purpoſe, conſiſting of ſeven ſmall veſſels. With theſe he ſailed in the ſpring of 1585, and reaching the coaſt of Florida in June, he left there a colony of one hundred men, and then ſailed homewards. He made other voyages, but when the nation was threatened with the dangers of a Spaniſh invaſion, he was appointed one of a council of war, to concert means of defence, and received the queen's commands not to quit the county of Cornwall, which prevented him from executing his intentions of making another voyage to the American coaſt. In 1591 he was appointed vice-admiral of a ſquadron, fitted out for the purpoſe of intercepting a rich Spaniſh fleet from the Weſt Indies. This fleet, when it appeared, was convoyed by a very ſuperior force, and Greenville was urged to tack about, but he preferred, and no doubt his ſailors agreed with him, taking chance of breaking through the enemy's fleet, which almoſt immediately ſurrounded him. The Spaniſh admiral, with four other ſhips, began a cloſe attack at three in the afternoon; the engagement laſted till break of day next morning, during which the Spaniards, notwithſtanding their vaſt ſuperiority, were driven off fifteen times. At length the greater part of the Engliſh crew being either killed or wounded, and the ſhip reduced to a wreck, no hope of eſcape remained. The brave commander had been wounded at the beginning of the action, but he cauſed his wounds to be dreſſed on deck, and refuſed to go down into the hold, and in that ſtate he was ſhot through the body. He was now taken to the cabin, and while in the act of being dreſſed, the ſurgeon was killed by his ſide. The admiral ſtill determined to hold out, wiſhing rather to ſink the ſhip than ſurrender, but the offers of quarter from the Spaniards induced the men to yield. Sir Richard was taken on board the Spaniſh ſhip, and honourably treated, but he died of his wounds in leſs than three days. His laſt words ſhew the temper of the hero, better than any eulogium that could be formed for him; they were ſpoken in the Spaniſh language, "Here die I, Richard Greenville, with a joyful and quiet mind; for that I have ended my life as a true ſoldier ought to do, fighting for his country, queen, religion, and honour; my ſoul departing from this body, leaving behind the laſting fame, of having behaved as every valiant ſoldier is in duty bound to do." This noble minded man has been blamed for raſhneſs; but exceſs of bravery, if ſuch it may be denominated, in a Britiſh ſeaman meets with a ready pardon, and ſuch examples as Greenville and a Nelſon, though not always to be juſtified on the ſcore of prudence, have effected more advantages for this ſea-girt iſland, than can be well deſcribed. Biog. Brit.

Greenville, *Sir* Bevil, grandſon of the preceding, was born in the year 1596. He was educated at Exeter college, Oxford, under the celebrated D. Prideaux, where he acquired a large ſtock of knowledge, and an ardent attachment to the eſtabliſhed religion of his country. When he came to his eſtate he diſtinguiſhed himſelf as a moſt reſpectable country gentleman, and ſat, very often, in parliament, as knight of the ſhire for the county of Cornwall, and burgeſs of Launceſton. In 1638, he attended the king with a troop of horſe, raiſed at his own expence, in an expedition to Scotland. For this ſervice he received at the hands of his ſovereign the honour of knighthood. He diſtinguiſhed himſelf during the civil wars, and had a command in the battle of Stratton, gained by Hopton againſt the earl of Stamford, in May 1643. He was preſent, and made a conſiderable ſtand in other engagements, particularly in that which was fought at Lanſdown, near Bath, in which the parliament forces were commanded by ſir William Waller. In this action ſir Bevil, at the head of his Corniſhmen, received a fatal blow with a pole-ax. His body was afterwards found, ſurrounded by thoſe of his officers; and it was obſerved, to the honour of the gentlemen of England, that there were more officers and gentry, than common men, ſlain on the king's ſide. Sir Bevil was extremely lamented: his character was drawn by lord Clarendon: "That which would have clouded any victory, was the death of ſir Bevil Greenville. He was, indeed, an excellent perſon, whoſe activity, intereſt, and reputation was the foundation of what had been done in Cornwall, and his temper and affection ſo public, that no accident which happened could make any impreſſion on him; and his example kept others from taking any thing ill, or at leaſt ſeeming to do ſo: in a word, a brighter courage and gentler diſpoſition were never married together, to make the moſt cheerful and innocent converſation." A monument was erected to his memory on the ſpot on which he fell. Biog. Brit.

Greenville, in *Geography*, a county in Waſhington diſtrict, South Carolina; ſituated in the N.W. corner of the ſtate; containing 11,504 inhabitants, of whom 1439 are ſlaves. This county is mountainous and hilly; but it is well watered, and the climate is pleaſant and healthy.—Alſo, a poſt-town of South Carolina, and chief town of Cheraws diſtrict; ſituated on the W. ſide of Great Pedee river, in Darlington county. It contains about 30 houſes, a court-houſe, gaol, and academy; 55 miles E.N.E. from Camden.—Alſo, a poſt-town and capital of Pitt county, North Carolina, on the S. bank of Tar river, diſtant 23 miles from Waſhington, and containing about 50 houſes, a court-houſe, a gaol, and a ſeminary, called the Pitt academy.—Alſo, a poſt-town of Mecklenburg county, Kentucky; 766 miles W. by S. from Waſhington.—Alſo, a poſt-town in Jefferſon county, Miſſiſſippi territory; 1217 miles from Waſhington.—Alſo, a ſmall poſt-town in Green county, in the ſtate of Teneſſee, ſituated on the W. ſide of the north-eaſternmoſt branch of Nolachucky river, about ſix miles N. by E. of Greenville college; 653 miles S.W. of Philadelphia.—Alſo, a fort and ſettlement in the ſtate of Ohio, on the S. ſide of a north-weſtern branch of the Great Miami, ſix miles N.W. of fort Jefferſon, on the ſame branch, about 23 miles S.E. of fort Recovery. It has baſtions at each angle, and is capable of accommodating 2000 men.

Greenville *Bay*, or *La Bay*, a town and port of entry on the E. or windward ſide of the iſland of Grenada. It has about 60 dwelling-houſes, a church, and ſeveral rich ſtores of Indian and European goods, and plantation utenſils. Its ſituation is low and rather unhealthy.

Greenville *College*, a college in Green county, in Teneſſee, founded in 1794, by the firſt act of the firſt aſſembly of the ſouth-weſtern territory. It is ſituated between two ſmall northern branches of Nolachucky river, not far from *Greenville*, (which ſee) the county town. Its local ſituation conduces very much to its utility, as it is retired, healthy, cheap, and near public roads in every direction. It is under the management of 14 truſtees, and poſſeſſes a library of between one and two thouſand volumes, and philoſophical apparatus, and a convenient building.

GREENWICH, a market-town and pariſh in the hundred of Blackheath, and county of Kent, England, is ſituated on the banks of the Thames, adjoining to Deptford, and 5½ miles diſtant from London. There are traces of a royal reſidence at Greenwich ſo early as the reign of Edward I., A.D. 1300. Henry IV. dated his will in 1408 from this manor, which was granted by Henry V. to Thomas duke of Exeter, after whoſe death it was conferred on Humphrey duke of Glouceſter, uncle to Henry VI., who, in 1433, gave the duke licence to fortify and embattle his manor-houſe, and to make a park of 200 acres; under this grant the duke rebuilt the palace, and incloſed the park, in which he erected a moated tower. On the duke's death in 1447, the manor reverted to the crown; and was a favourite reſidence of Edward IV., who enlarged and finiſhed the palace. Henry VII. ſpent much of his time at Greenwich, where his two ſons, Henry and Edmund, were born. Henry VIII. made conſiderable additions to the buildings, and during his reign Greenwich became one of the principal ſcenes of that feſtivity for which his court was celebrated. Tournaments and revels were frequently held; and in 1513 the firſt maſquerade ever ſeen in England was here introduced. Edward VI. kept his Chriſtmas here in 1552, and died in this palace in July following. The queens, Mary and Elizabeth, were both born here, and the latter chriſtened with peculiar ſtate. She was particularly partial to this manſion, and made it her ſummer reſidence, paſſing the feſtive hours of that romantic period in various diverſions and ſplendid exhibitions. This palace was frequently viſited by James I. and Charles I.; was afterwards aſſigned by parliament to the Protector; and, after the reſtoration, again devolved, with the park and appendages, to the crown: when the king, finding the whole building in a ruinous ſtate, ordered it to be pulled down, and commenced a magnificent palace of free-ſtone on its ſcite, under the direction of Webb, the ſon-in-law of Inigo Jones, from whoſe papers the deſigns are ſaid to have been made. One wing, however, was all that was completed, at the expence of 36,000*l.*, in which the king occaſionally reſided; but no further progreſs was made in the building either in that or the ſucceeding reign. Soon after the acceſſion of William and Mary, a project was formed for providing an aſylum for aged and diſabled ſeamen;

men; and their majeſties having reſolved to carry it into execution, ſir Chriſtopher Wren recommended that the unfiniſhed palace at Greenwich ſhould be completed and enlarged for this purpoſe. His advice being adopted, he contributed his time and abilities in the ſuperintendance of the works for ſeveral years without any emolument. Such was the origin of Greenwich hoſpital, of which the foundation was laid June 3, 1696, and which has been gradually enlarged and improved, till it arrived at its preſent height of magnificence. The hoſpital is a ſplendid and extenſive ſtructure, principally built with Portland ſtone, and conſiſts of four diſtinct quadrangular piles of buildings, diſtinguiſhed by the names of the reſpective ſovereigns, in whoſe reigns they were founded or built. The grand front opens on a terrace, ſkirting the ſouthern bank of the Thames, and extends 865 feet in length, in the centre of which is a deſcent to the river, by a double flight of ſteps. The ground plan of the whole edifice forms nearly a ſquare; of which king Charles's building occupies the north-weſt angle; queen Anne's, the north-eaſt; king William's, the ſouth-weſt; and queen Mary's, the ſouth-eaſt. The interval between the two former buildings forms a ſquare 270 feet wide, in the middle of which is a ſtatue of George II., ſculptured by Ryſbrach, out of a ſingle block of white marble, which weighed eleven tons, and was taken from the French by admiral ſir George Rooke: this ſtatue was given to the hoſpital by ſir John Jennings, who was governor from 1720 to 1744. The ſpace between the two latter buildings which include the hall and chapel, with their elegant domes, and the two colonnades, forms a leſſer ſquare, apparently terminated by the ranger's lodge in the park. The two ſquares are interſected by a ſpacious avenue, leading from the town through the hoſpital. The buildings which immediately front the Thames have a general correſpondence in ſtyle and arrangement. The north and ſouth fronts of each exhibit the appearance of a double pavilion, conjoined above by the continuation of an Attic order, with a baluſtrade, which ſurmounts the whole, but is ſeparated below by an open portal: the centre of each pavilion diſplays an elegant pediment, ſupported by four Corinthian columns, and the ſides a double pilaſter of the ſame order. King Charles's building contains the apartments of the governor and lieutenant-governor, the council-room, and anti-chamber; with fourteen wards, wherein 300 penſioners may be accommodated. In the council-room are ſeveral portraits: in the anti-chamber two large ſea-pieces, given to the hoſpital by Philip Harman, eſq., repreſenting the exploits of his anceſtor captain Thomas Harman of the Tyger frigate, in the reign of Charles II.; and a ſeries of ſix ſmall pieces, deſcriptive of the loſs of the Luxemburgh galley, in the year 1727. Queen Anne's building contains ſeveral apartments for inferior officers, with twenty-four wards, for four hundred and thirty-ſeven penſioners. King William's building ſtands to the ſouth-weſt of the great ſquare, and compriſes the great hall, veſtibule, and dome, deſigned and erected by ſir Chriſtopher Wren, between the years 1698 and 1703. To the eaſt of theſe adjoins a colonnade, three hundred and forty-ſeven feet in length, ſupported by Doric columns, and pilaſters twenty feet in height. The great hall is one hundred and ſix feet in length, fifty-ſix in width, and fifty high: the cieling and ſides are covered with portraits and emblematical figures, executed by ſir James Thornhill, for which he was paid at the rate of 3*l.* per ſquare yard for the cieling, and 1*l.* for the ſides, amounting in the whole to 6685*l.* The weſt front of King William's building, which is of brick, was finiſhed about 1725 by ſir John Vanbrugh: the building contains eleven wards, wherein are five hundred and fifty-one beds. The foundation of the eaſtern colonnade, which is ſimilar to that on the weſt ſide, was laid in 1699; but the chapel, and the other parts of queen Mary's building which adjoin to it, were not finiſhed till 1752. It correſponds with king William's, and is furniſhed with one thouſand and ninety-two beds, in thirteen wards. The preſent chapel, one of the moſt elegant ſpecimens of Grecian architecture in this kingdom, was erected from the claſſical deſigns of the late James Stuart, eſq., better known, perhaps, by the appellation of "Athenian Stuart," which he acquired from the Attic elegance of his buildings, and his intereſting publication on the antiquities of Athens. The chapel is one hundred and eleven feet in length, and fifty-two in width, and is capable of accommodating one thouſand penſioners, nurſes, and boys, excluſive of the ſeats for the directors and other officers. The portal conſiſts of an architrave, frieze, and cornice, of ſtatuary marble: the folding-doors are of mahogany, highly enriched by carving. The interior is finiſhed in an elegant ſtyle; and is adorned with many appropriate paintings; the moſt diſtinguiſhed of which is the altar-piece, executed by Weſt, and repreſenting the preſervation of St. Paul, on the iſland of Melita; a ſubject peculiarly adapted to this eſtabliſhment. Without the walls of the hoſpital ſtands the Infirmary, erected in 1763, after a deſign by Stuart: it forms an oblong quadrangle, one hundred and ninety-eight feet long, and one hundred and ſeventy-five broad; and conſiſts of two ſtories for the reception reſpectively of thoſe whoſe caſes require ſurgical aid, and of thoſe who are in need only of medical aſſiſtance. It contains ſixty-four rooms, each is fitted up for the accommodation of four patients. It alſo includes a chapel, hall, kitchen, and apartments for the phyſician, ſurgeon, and apothecary; with hot and cold baths, and other neceſſary offices. The penſioners, who are the objects of this noble charity, muſt be ſeamen diſabled by age, or maimed, either in the king's ſervice, or in the merchant ſervice, if the wounds were received in defending or taking any ſhip, or in fight againſt a pirate; foreigners who have ſerved two years in the Britiſh navy, become entitled to the benefits of this inſtitution in the ſame manner as natives. The widows of ſeamen are provided for, having the excluſive privilege of being nurſes in the hoſpital. The number of penſioners is upwards of 2400, who are furniſhed with clothes, diet, and lodging, with a ſmall allowance of pocket-money. The nurſes are 144, each of whom receives eight pounds per annum as wages, with every neceſſary of life. The governors of the hoſpital are about 100, and conſiſt of all the great officers of ſtate, the archbiſhops, the lord chancellor, the judges, the maſter and five ſenior brethren of Trinity-houſe, the lord mayor, and three ſenior aldermen of London, with ſome of the principal officers of the hoſpital. The annual average expence of each penſioner, according to the report of the commiſſioners of naval enquiry, was eſtimated at 27*l.* 10*s.* 9*d.* *per* man; and of the nurſes, 29*l.* 15*s.* 0*d.* each; the total annual expence being 69.206*l.* 5*s.* The funds of the eſtabliſhment are principally derived from a duty of ſixpence *per* month, paid by every mariner, either in the king's or merchant's ſervice; the forfeited eſtates of the earl of Derwentwater; and various benefactions from different ſovereigns, from parliament, and from private perſons.

The old tower at Greenwich, built by duke Humphrey, temp. Henry VI. was pulled down in 1675, by order of Charles II., who founded on its ſcite the preſent Royal Obſervatory, for the purpoſe of aſcertaining the motions of the moon, and the places of the fixed ſtars, in order to facilitate the attempts to diſcover the longitude at ſea.

Mr. Flamſteed, the firſt aſtronomer royal, began his obſervations in September 1676, and did ample juſtice to his appointment, though walking in an almoſt untrodden path, and not having, till 1689, the advantage of a mural quadrant, and even then not ſuch as is now in uſe, but one contrived by himſelf. He died in December 1719, and was ſucceeded by Dr. Halley, who fixed a tranſit inſtrument, and had a new mural quadrant of eight feet radius, conſtructed by Graham. On the death of Dr. Halley, in 1742, Dr. Bradley was appointed: in his time very valuable additions were made to the inſtruments at the obſervatory. Dr. Bradley, dying in 1762, was ſucceeded by Mr. Bliſs, whoſe deceaſe, in 1764, made room for the advancement of Dr. Maſkelyne, the preſent aſtronomer royal, who has diſplayed eminent ability in his ſituation. Since his appointment, the obſervatory has been furniſhed with an excellent achromatic teleſcope, of forty-ſix inches, focal length, with a treble object glaſs, &c. by Dollond; and the whole aſtronomical apparatus has been greatly improved by Dollond, Nairne, and Arnold. The obſervations made by the aſtronomer royal have been, ſince 1767, publiſhed annually under the inſpection of the Royal Society, who have the power of viſiting the obſervatory every year, to ſee that the inſtruments are kept in proper order.

The *church* at Greenwich is dedicated to St. Alphage, archbiſhop of Canterbury, who is ſaid to have been killed by the Danes on its ſcite: it is one of the fifty new churches erected in the reign of queen Anne; the old church having become ſo ruinous by lapſe of time, that the roof fell in about midnight, November 28, 1710. At the end of the town is the duke of Norfolk's college, for the maintenance of 20 decayed houſekeepers. Here is alſo an hoſpital for 20 poor perſons, founded by Mr. Lambarde, author of the "Perambulation of Kent," and called queen Elizabeth's college. There was a convent of friars at Greenwich, founded about the time of Edward IV. For many years here was a conſiderable powder magazine, which, after repeated application to parliament by the inhabitants, was removed to Purfleet in Eſſex, in 1760.

The population of Greenwich, as returned under the late act, was 14,339: the number of houſes 2,121; many of theſe are handſome buildings; the ſtreets are irregular, and the whole town is interſected by the hoſpital and its precincts. Fairs for three days are held at Eaſter and Whitſuntide; and well ſupplied markets every Wedneſday and Saturday. Lyſons's Environs of London, vol. iv. Beauties of England and Wales, vol. vii.

Greenwich, a townſhip of America, in Hampſhire county, Maſſachuſetts, incorporated in 1754, and containing 1,460 inhabitants; 20 miles E. from Northampton.—Alſo, a townſhip in Glouceſter county, New Jerſey, on the E. bank of Delaware river, oppoſite to Fort Mifflin; 6 miles S. E. of Philadelphia.—Alſo, a townſhip in Suſſex county, New Jerſey, on the E. ſide of Delaware river, in a mountainous country, 31 miles S. W. of Newton; it contained, in 1790, 2,035 inhabitants.—Alſo, a town in Cumberland county, New Jerſey, on the N. W. bank of Cohanzy creek, about 3 miles from its mouth, in Delaware bay, containing about 80 houſes and a Friends' meeting-houſe; 66 miles S. by W. from Philadelphia.—Alſo, a maritime and poſt-town in Fairfield county, Connecticut, 40 miles E. of New York, and containing 3,147 inhabitants. —Alſo, a town in Waſhington county, New York, on the E. bank of Hudſon's river. At the ſaw-mills of this town much buſineſs is done.

Greenwich, *Eaſt*, a poſt-town, and the chief townſhip in Kent county, Rhode iſland, diſtant 16 miles S. from Providence, and containing 1,775 inhabitants. It includes a meeting-houſe and a handſome court-houſe; and though its commerce is much reduced, it derives advantage from its fiſheries, and ſends ſome veſſels to the Weſt Indies. It is ſituated on the N. W. part of Narraganſet bay. It is noted for it good cyder, and formerly raiſed tobacco for exportation.

GREENWOOD, a townſhip in Cumberland county, Pennſylvania, having 724 inhabitants.—Alſo, a townſhip in Mifflin county, in the ſame ſtate, containing 969 inhabitants.

Green woods, a large foreſt of ſtately pines in Litchfield county, Connecticut, covering part of that county, and clothed in a green bearded moſs, which gives to the whole a gloomy, wild, and whimſical appearance.

GREES, a river of Ireland, in the county of Kildare, which flows by the pretty town of Ballitore, and joins the Barrow; 6 miles S. from Athy.

GREESA, a town in Algiers; 30 miles E. S. E. of Tiffeſh.

GREGARIOUS Birds, are ſuch as do not live ſolitarily, but aſſociate in flights or coveys, a great many together in company.

Gregarious, in *Geology*, is applied to ſuch reliquia or extraneous foſſils, found imbedded in the ſtrata, as are congregated a great number of the ſame ſpecies together, which very commonly is the caſe, particularly in calcareous rocks.

GREGGIA, in *Botany*, ſo named by the late Dr. Solander, in compliment to Mr. John Greg, a gentleman long reſident in Dominica, the correſpondent of Ellis, Garden, and other naturaliſts of his day. He ſent many plants to Kew and other collections, and returned to England about the year 1784, dying ſome years afterwards, at his ſeat near Hampton Court.—Gærtn. t. 33. (Myrtus Gregii; Swartz. Ind. Occ. 896. Ait. Hort. Kew. vol. ii. 159. Mart. Mill. Dict. v. iii.) See Myrtus.

GREGOIE, or Grebou, in *Geography*, a ſmall iſland of Africa, in the river Jacquin, about a league from the ſea, on the Gold Coaſt, where the European nations have factories.

GREGORIAN Calendar. See Calendar.

Gregorian *Chant*. See Chant.

Gregorian *Code*. See Code.

Gregorian *Epocha*, is the epocha, or time, whence the Gregorian calendar or computation took place. The year 1810 is the 228th year of the Gregorian epocha.

Gregorian *Notes*, in *Eccleſiaſtical Muſic*. In the Romiſh miſſals, breviaries, antiphonaries, and graduals, only four lines are uſed in the notation of the chants; with two clefs, the baſe and tenor, or thoſe of F and C, which are removable; and two kinds of notes, the ſquare and the lozenge; the firſt for long ſyllables, and the ſecond for ſhort. In ſome modern French miſſals a third ſpecies of note is uſed, generally at a cloſe; this is ſquare with a tail added to it, and is of longer duration than either of the other two. However, the Italians ſeldom uſe any other than ſquare notes in their canto fermo, nor did the French, in their more ancient books.

Theſe characters are not ſuppoſed to have been invented by St. Gregory, nor were they in uſe till many ages after his time; but ſince their invention, having been appropriated chiefly to the purpoſe of writing eccleſiaſtical chants in the antiphonary of that pontiff, they obtained the appellation of Gregorian notes.

Gregorian *Year*. See Year.

GREGORIO *de Puerto Viejo*, in *Geography*, a diſtrict and town of South America, in the audience of Quito, and juriſdiction of Guayaquil.

GREGORIO, *St.* a town of Naples, in Principato Citra; 8 miles N. W. of Cangiano.

ST. GREGORIO *de Abo*, a town of New Mexico; 110 miles S. of Santa Fé.

GREGORIUS, in *Ichthyology*. See SALMO *lavarctus*.

GREGORY I. in *Biography*, pope, ſurnamed the Great, and alſo dignified with the title of Saint, was a native of Rome, and born about 544 or 5. He was deſcended from one of the moſt illuſtrious families in that city, and was educated in a manner ſuitable to his rank. His proficiency in literary purſuits anſwered the moſt ſanguine expectations of his friends; it was ſaid that none in Rome excelled him in grammar, rhetoric, and logic. Having left the uſual routine of ſchool learning, in the courſe of which he had imbibed ſentiments of deep piety, as well as the elementary principles of knowledge, he paid particular attention to the ſtudy of juriſprudence, which was neceſſary to perſons who filled thoſe ſtations, to which he was entitled by his birth. When he came under public notice, he diſcovered ſuch abilities, integrity, and prudence, in the exerciſe of the different ſenatorial employments, that the younger Juſtin, who was emperor, appointed him to the honourable poſt of governor of Rome. In this office he acquitted himſelf to the ſatiſfaction of the emperor, of the ſenate, and of the people. At the death of his father, he became poſſeſſed of immenſe wealth, and being, probably from ſome diſappointments, diſguſted with the world, he determined to embrace the religious life. He devoted the greater part of his property to the foundation of religious houſes, and to charitable purpoſes. He founded ſix monaſteries in Sicily, and one at Rome in his father's houſe, dedicated to St. Andrew, over which he conſtituted Valentius abbot, whom he had ſelected for that poſt from a country monaſtery, and to whoſe diſcipline he ſubmitted himſelf. From the time of his taking the vows, he abandoned himſelf to meditation, devotion, and the moſt rigorous abſtinence. He was, however, in the year 579 taken from his retreat, ordained deacon, and ſent nuncio from the pope to the imperial court: the object of this miſſion was to apply for relief in behalf of the inhabitants of Italy, againſt the ravages of the Lombards. So ably did he conduct the buſineſs, that the emperor was entirely ſatisfied, and Gregory became one of his principal favourites: he was equally beloved by the principal courtiers, and even by the biſhops, notwithſtanding the jealouſy which they uſually entertained of a pope's nuncio. While he was at Conſtantinople, he had a diſpute with the patriarch Eutychius, on the queſtion, Whether, after the reſurrection, the bodies of the righteous would or would not be palpable. The argument was carried on in the preſence of the emperor Tiberius; Gregory mantained the affirmative ſide of the queſtion, to which the emperor gave his decided ſanction, at the ſame time, he ordered the patriarch to acquieſce in the judgment, and condemned to the flames a treatiſe of that prelate in ſupport of the negative ſide of the queſtion. In 583 Gregory was recalled to Rome, and appointed ſecretary to pope Pelagius, until he obtained permiſſion to retire to his monaſtery. He was choſen abbot; and in that office exacted of his monks as ſtrict an obſervance of rigorous abſtinence and diſcipline, as he practiſed himſelf. After a ſhort exerciſe of the monaſtic virtues, he was dragged from the cloiſter to the papal throne, by the unanimous voice of the clergy, the ſenate, and the people. He alone reſiſted his own elevation: and his humble petition, that the emperor would be pleaſed to reject the choice of the Romans, could only ſerve to exalt his character in the eyes of the emperor and the public, and he not only confirmed the wiſhes of the people, but congratulated the Romans on the choice which they had made. When the mandate was proclaimed, Gregory ſolicited the aid of ſome friendly merchants to convey him in a baſket beyond the gates of Rome, and he concealed himſelf a few days in the mountains, and among the woods, where he believed, or affected to believe, that he ſhould be ſafe from diſcovery. Notwithſtanding this precaution, he was in a few days found in a cave, and brought back in triumph by the people, who would not abandon their charge, till they had taken him to the church of St. Peter, where he was inſtantly ordained. The pontificate of Gregory the Great, which laſted rather more than ſix years and a half, is reckoned one of the moſt flouriſhing periods of the church; his virtues, and even his failings, were happily ſuited to his ſtation, and to the temper of the times. His firſt ſtep was to ſatisfy the biſhops of the chief ſees, as to the orthodoxy of his faith. For this purpoſe, he wrote to the patriarchs of Conſtantinople, Alexandria, Antioch, and Jeruſalem, declaring that he received the firſt four councils as the four books of the holy goſpel; that he reverenced the fifth, and that he condemned the three chapters. In his rival, the patriarch of Conſtantinople, he condemned the Anti-chriſtian title of univerſal biſhop, which the ſucceſſor of St. Peter was too haughty to concede, and too feeble to aſſume; and the eccleſiaſtical juriſdiction of Gregory was confined to the triple character of biſhop of Rome, primate of Italy, and apoſtle of the Weſt. He frequently aſcended the pulpit, and kindled by his eloquence the congenial paſſions of his audience: the language of the prophecies of the Old Teſtament he interpreted and applied, and he took the opportunity of improving the preſent calamities of the people, by directing their hopes and anxieties to the inviſible world. His precepts and example defined the model of the Roman liturgy; the diſtribution of the pariſhes, the calendar of feſtivals, the order of proceſſion, the ſervice of the prieſts and deacons, the variety and change of ſacerdotal garments. Till almoſt the laſt period of his life, he officiated in the canon of the maſs, which continued above three hours at a time. Gregory was no friend to heretics: he ſpared no pains to arm the civil and eccleſiaſtical power againſt the Donatiſts in Africa, and all who favoured them. At firſt, he was defeated in his wiſhes to deſtroy the harmony that ſubſiſted between the Catholic and Donatiſt parties in that country: he contrived to introduce invidious diſtinctions, which by degrees renewed the animoſities by which they had been formerly diſtracted, and terminated in the ultimate triumph of the Catholic, which was the ſtrongeſt party. Notwithſtandiug the zeal of pope Gregory againſt the heretics, he was favourable to the Jews, and protected them againſt ſome violent Chriſtians. In certain letters, which he wrote to the biſhops who were for forcing them to embrace Chriſtianity, he condemned perſecution of all kinds in the ſtrongeſt terms, though he enforced it in the inſtance of Chriſtians, who ventured to differ from the Catholic creed. On his acceſſion to the papal throne, a general relaxation of diſcipline, as well as of piety and morals, prevailed in the clerical orders: he immediately ſet about the correction of theſe evils with the utmoſt diligence and perſeverance. While Gregory was enforcing reformation on the clergy, he ſet before them an example of the conduct which he preſcribed. He was ſtrictly attentive to the duties of piety: he was humble, mild, compaſſionate, hoſpitable, and diſintereſted, an enemy to all pomp, grandeur, and ſhow, frequently abridging himſelf of the neceſſaries of life to relieve the indigent, and was moſt indefatigable in inſtructing his flock, both by preaching and writing. With all his humility, however, Gregory was a moſt zealous aſſertor of the power and prerogatives which his predeceſſors had exerciſed, or at any time claimed. He would declare, and no one ſeemed to doubt the ſincerity of his aſſertion, that he would rather loſe his life, than ſuffer the ſee of St. Peter to forfeit any of the privileges which it had ever enjoyed, or the prime apoſtle to be any ways injured, or robbed of his rights. In the year 593, the emperor iſſued an edict, forbidding any ſoldiers to quit the army, under the pretence of embracing a monaſtic life, till the time of their ſervice was expired. The pope determined to remonſtrate againſt the decree, being perſuaded that the eccleſiaſtical road was more ſafe than any other to the attainment of a heavenly crown. For this and ſome other acts of interference, the emperor expreſſed his diſſatisfaction with the ſteps taken by the pope, in ſtrong and even abuſive terms, and they proved the means of fruſtrating his application for a redreſs of grievances occaſioned by the cruelty and avarice of the imperial officers. The king of the Lombards threatened to lay ſiege to Rome, in order that he might avenge himſelf of ſome circumſtance that had happened contrary to his dignity, but Gregory made friends with his favourites, who had themſelves embraced the Catholic faith, and by their interceſſions the prince was induced to draw off his troops. About this time the patriarch of Conſtantinople aſſumed the title of "Univerſal Patriarch," a meaſure which alarmed Gregory, who made every exertion to prevent him from making good his claims. All his entreaties were vain, the patriarch eſtabliſhed his title, and entailed it on his ſucceſſors. When Gregory was informed of this he renounced the patriarch's communion, and condemned his conduct on the occaſion as vain, ambitious, profane, impious, execrable, anti-chriſtian, blaſphemous, infernal, and diabolical. In the year 596, Agilulph, king of the Lombards, broke into the imperial territories, laying waſte the Roman dukedom of Campania, and carrying away the inhabitants into captivity. On this occaſion Gregory exerciſed the moſt unbounded charity, in relieving the poor, and redeeming great numbers of priſoners, not only applying the revenues of his ſee to thoſe benevolent purpoſes, but large ſums which he obtained by his application to the biſhops, and the great men who were his friends, both in the Eaſt and Weſt. Under his reign the Arians of Italy and Spain were reconciled to the Catholic church, and the conqueſt of Britain reflects leſs glory on the name of Cæſar than on that of Gregory I. Inſtead of ſix legions, forty monks were embarked for that diſtant iſland, and the pontiff lamented the auſtere duties which forbade him to partake the perils of their ſpiritual warfare. In leſs than two years he could announce to the archbiſhop of Alexandria, that they had baptized the king of Kent with ten thouſand of his Anglo-Saxons, and the Roman miſſionaries, like thoſe of the primitive church, were armed only with ſpiritual and ſupernatural powers. The credulity or the prudence of Gregory was always diſpoſed to confirm the truths of religion by viſions and pretended miracles, and he accordingly acquired a high reputation with his own and ſucceeding ages. The patriarch of Conſtantinople dying, he was ſucceeded by Cyriacus, whoſe faith was deemed orthodox by the pope, but who perſiſted in claiming the title "Univerſal Patriarch." Gregory ſtill reſiſted, and in the courſe of the correſpondence which he maintained with the patriarchs of Antioch and Alexandria to intereſt them on his ſide of the diſpute; the laſt mentioned prelate gave him the title of "Univerſal Pope," in hopes thereby of terminating the difference between the contending parties. Gregory, however, rejected the title with great indignation, and by way of contraſt to the patriarch's conduct, he adopted the appellation of "Servant of Servants," which his ſucceſſors have retained to this day, and affected to uſe it even when diſtinguiſhed by the moſt ſcandalous exerciſe of pride and deſpotiſm. In the year 1601, at the requeſt of Auguſtin, the pope ſent a freſh colony of monks into Britain, and with ſuch directions to that apoſtle of the Anglo-Saxons, as he has been denominated, as have proved the means of introducing the groſſeſt corruptions and ſuperſtitions into the ſyſtem of Chriſtianity eſtabliſhed through his miſſion. During this ſame year Serenus, biſhop of Marſeilles, ordered all the images throughout his dioceſe to be caſt out of the churches and deſtroyed: his conduct was not quite approved by Gregory, though he pretended to applaud Serenus's zeal, in not ſuffering any thing to be worſhipped that is made with hands. Nevertheleſs, he condemned his caſting them out of the churches and daſhing them to pieces, as the effect of an inconſiderate and indiſcreet zeal, obſerving, that "though images were not ſet up in the churches to be worſhipped, yet they ſerve to inſtruct the ignorant: and it is one thing to adore an image, and another to learn from an image what is to be adored." During the year 602 a revolution took place at Conſtantinople, in conſequence of the revolt of the army, at the inſtigation of Phocas, a centurion, who was proclaimed emperor, and obtained poſſeſſion of the imperial city and throne. The firſt object of the new ſovereign was to deſtroy the abdicated prince, with his ſix ſons and a number of his relations and friends, and then he got himſelf acknowledged lawful emperor in all parts of the empire. On this occaſion, Gregory expreſſed his utmoſt ſatisfaction and joy at the change that had taken place, without hinting that he felt any ſorrow at the means by which it had been accompliſhed. He immediately wrote letters to the new emperor, congratulating him on his acceſſion to the imperial crown, which he ſaid was effected by a particular providence, to deliver the people from the oppreſſions under which they had ſo long groaned, and he even commended, flattered, and extolled the tyrant, for his juſtice, clemency, and piety, in the moſt fulſome terms. His object in this abject behaviour was that he might, by means of the influence of the emperor, defeat the attempt of the patriarch to aſſume the title of "Univerſal Biſhop." This he plainly told to Leontia, the new empreſs, repreſenting to her what bleſſings they might expect from St. Peter in heaven, provided they obliged the patriarch to relinquiſh the title, which the pope conſidered derogatory to the honour, dignity, and intereſts of his ſee. In this object he ſucceeded, for Phocas enacted a law, by which he prohibited the biſhop of Conſtantinople from ſtyling himſelf oecumenical or general patriarch, declaring that this title belonged to none but the biſhop of ancient Rome. This was not the only inſtance in which Gregory condeſcended to flatter baſe and infamous characters: he ſhewed equal or even greater complaiſance to Brunchaut, queen of France, who is deſcribed by Bayle as the moſt wicked woman upon earth, but as capable of winning over the clergy to her intereſt, becauſe at the ſame time that ſhe committed the moſt enormous crimes, ſhe was exceſſively liberal to eccleſiaſtics, and founded temples and convents, not forgetting to ſue very devoutly for relics to the holy father. In all the letters which the pope wrote to her, he treated her with the moſt abject flattery, declaring that no nation in the world was ſo happy as the French, ſince it merited ſuch a queen, endowed with virtues and fine qualities of every kind. In the year 604, Gregory was attacked with a ſevere fit of the gout, a diſorder to which he had been accuſtomed, and which rendered him incapable of performing the duties of his high office. Ambaſſadors were ſent to him from the queen of the Lombards, announcing the birth and baptiſm of her ſon: he was unable to write an anſwer to her majeſty, with regard to ſome difficulties which ſhe wiſhed to have ſolved, but he returned by her ambaſſador, a complimentary note, containing commendations of her zeal for the Catholic faith, and with preſents to the new-born prince, of a croſs to wear at his neck, in which was encloſed a piece of the true croſs, as he was pleaſed to affirm, together with the goſpel, in a Perſian box. This was one of the laſt acts of the pope. He died in the month of March 604. Such were the tranſactions of Gregory I. who has, for his talents and merits, been ſurnamed the Great. There was, however, a ſtrange mixture of inconſiſtencies in his character. In ſome reſpects he diſcovered a ſound and penetrating judgment, but in others the moſt ſhameful and ſuperſtitious weakneſs. He was no friend to ſecular and polite learning: he has even been accuſed of having deſtroyed the noble monuments of the ancient magnificence of the Romans, leſt travellers and foreigners, who came to viſit Rome on religious motives, by paying undue attention to them, ſhould neglect the holy places. This accuſation does not ſtand on undeniable evidence. It is doubted by Gibbon and other well-informed hiſtorians. "The writings of Gregory," ſays Mr. Gibbon, "reveal the implacable averſion to the monuments of claſſic genius; and he points his ſevereſt cenſure againſt the profane learning of a biſhop, who taught the art of grammar, ſtudied the Latin poets, and pronounced with the ſame voice the praiſes of Jupiter and thoſe of Chriſt. But the evidence of his deſtructive rage is doubtful and recent; the temple of peace, and the theatre of Marcellus, have been demoliſhed by the ſlow operation of ages, and a formal proſcription would have multiplied the copies of Virgil and Livy in the countries which were ſubject to the eccleſiaſtical dictator." Gregory invented new offices for the ſervices of the church, and the ſacraments, in which he preſcribed a vaſt number of rites and ceremonies that were unknown before his time. He took great pains in reforming the pſalmody of the church, inſtituting an academy of choiriſters, whom he taught to chant, and for whoſe uſe he compoſed that muſic which goes by his name. He left more writings behind him than any other pope from the foundation of the ſee of Rome to the preſent period. Theſe conſiſt of twelve books of "Letters," amounting to upwards of eight hundred in number. "A comment on the book of Job," generally known by the name of "Gregory's Morals on Job." "A Paſtoral," or a treatiſe on the duties of a paſtor. This work was held in ſuch veneration by the Gallican church, that all the biſhops were obliged, by the canons of that church, to be thoroughly acquainted with it, and punctually to obſerve the rules contained in it. He was author alſo of "Homilies" on the prophet Ezekiel; and on the goſpels, and of four books of "Dialogues." His works have been printed over and over again, in almoſt all forms, and at a number of different places on the continent, as Lyons, Paris, Rouen, Baſil, Antwerp, Venice, and Rome. The beſt edition is that of Paris, in 1705, in four vols. folio. The charity and wealth of this pontiff have already been referred to: in the uſe of his abundant riches, he acted like a faithful ſteward of the church and poor. The voluminous accounts of his receipts and diſburſements were kept above three hundred years in the Lateran as the model of Chriſtian economy. On the four great feſtivals, he divided their quarterly allowance to the clergy, to his domeſtics, to the monaſteries, to the churches, the places of burial, the alms'-houſes, and the hoſpitals of Rome, and the reſt of the dioceſe. On the firſt day of every month he diſtributed to the poor, according to the ſeaſon, their ſtated portion of corn, &c.; and his treaſurers were continually ſummoned to ſatisfy in his name the extraordinary demands of indigence and merit. The diſtreſs of the ſick and helpleſs, of ſtrangers and pilgrims, was relieved by the bounty of each day and of every hour, nor would the pontiff indulge himſelf in a frugal repaſt till he had ſent the diſhes from his own table to ſome objects deſerving of his compaſſion. The miſery of the times had reduced the nobles and matrons of Rome to accept, without a bluſh, the benevolence of the church. Three thouſand virgins received their food and raiment from the hand of their benefactor, and many biſhops of Italy eſcaped from the barbarians to the hoſpitable abode of the Vatican. Gregory might juſtly be ſtyled the father of his country, and ſuch was the extreme ſenſibility of his conſcience, that, for the death of a beggar, who had periſhed in the ſtreets, he interdicted himſelf during ſeveral days from the exerciſe of ſacerdotal functions. Moreri. Gibbon. Lardner.

Eccleſiaſtical writers ſeem unanimous in allowing that it was the learned and active pope Gregory the Great, who collected the muſical fragments of ſuch ancient hymns and pſalms as the firſt fathers of the church had approved, and recommended to the primitive Chriſtians; and that he ſelected, methodized, and arranged them in the order which was long continued at Rome, and ſoon adopted by the chief part of the weſtern church.

The anonymous author of his life, publiſhed by Caniſius, ſpeaks of this tranſaction in the following words: "This pontiff compoſed, arranged, and conſtituted the *Antiphonarium* and chants uſed in the morning and evening ſervice." Fleury, in his Hiſt. Eccl. tom. vii. p. 150, gives a circumſtantial account of the *Scola Cantorum*, inſtituted by St. Gregory. It ſubſiſted 300 years after the death of that pontiff, which happened in 604, as we are informed by John Diaconus, author of his life. The original Antiphonarium of this pope was then ſubſiſting; and the whip with which he uſed to threaten to ſcourge the boys; as well as the bed on which he reclined in the latter part of his life, when he viſited the ſchool in order to hear them practiſe. Two colleges were appropriated to theſe ſtudies; one near the church of St. Peter, and one near that of St. John Lateran; both of which were endowed with lands.

It has been imagined that St. Gregory was rather a compiler than a compoſer of eccleſiaſtical chants, as muſic had been eſtabliſhed in the church long before his pontificate; and John Diaconus, in his life, (lib. i. cap. 6.) calls his collection "Antiphonarium Centonem," the ground-work of which was the ancient Greek chant, upon the principles of which it was formed. This is the opinion of the Abbé Lebœuf, (Traité Hiſtorique et Pratique ſur le Chant Eccleſiaſtique, chap. iii.) and of many others. The derivation is reſpectable; but if the Romans in the time of St. Ambroſe had *any* muſic, it muſt have been compoſed upon the Greek ſyſtem: all the arts at Rome, during the time of the emperors, were Greek, and chiefly cultivated by Greek artiſts; and we hear of no muſical ſyſtem in uſe among the Romans, or at leaſt none is mentioned by their writers on the art, but that of the Greeks.

GREGORY II., pope, was a native of Rome, and educated from childhood, in the Lateran palace, under pope Sergius, who appointed him his ſub-deacon, almoner, and librarian. He was afterwards raiſed to higher poſts in the church, and was ſelected by pope Conſtantine, as the moſt learned man of his time, to accompany him when he went to Conſtantinople, in the year 710. In that city Gregory diſtinguiſhed himſelf by anſwering certain difficulties propoſed to him by the emperor Juſtinian, and ſolving his doubts with regard to ſome queſtions in which, it ſhould ſeem, he was much intereſted, though what thoſe difficulties were we are not informed. Upon the death of Conſtantine, in 715, he was raiſed to the papal dignity, and almoſt immediately upon this event, the Lombards made an irruption into the imperial territories, and took by ſurpriſe the city of Cumæ. Gregory, in his quality of Holy-Father, endeavoured to prevail on them to reſtore it, firſt by threatenings of the vengeance of heaven if they ſhould prove ſo wicked as to retain it, and afterwards by the offer of a large ſum of money, and the particular protection of St. Peter, provided they withdrew their troops, and abſtained from all farther hoſtilities. Finding that they were equally deaf to the threatenings and promiſes of the pope, he applied for the aſſiſtance of the king of Naples, who, for a ſtipulated ſum, undertook to recover the place, and ſucceeded in the enterpriſe. In the year 717, the emperor Theodoſius, having reſigned the imperial dignity, and retired to a monaſtery, Leo, the Iſaurian, was, by the ſenate and army, raiſed to the throne, on which occaſion he wrote a letter to the pope, accompanied with a confeſſion of faith, and alſo with promiſes to maintain the Catholic doctrine, as defined by the ſix general councils and the fathers. Gregory, in return, congratulated the emperor, in warm expreſſions of reſpect and loyalty, upon his acceſſion, and aſſured him, that he would not only receive him for his ſovereign, but would uſe his influence to preſerve peace and amity between him and all the Chriſtian princes of the Weſt. In 721, Gregory held a council at Rome, in which ſeveral important canons were enacted on the ſubject of unlawful marriages and other points relating to eccleſiaſtical diſcipline. While this council was ſitting, Winifrid, afterwards archbiſhop of Mentz, and known by the name of Boniface, arrived on a pilgrimage at Rome, where he was received with extraordinary marks of reſpect. A few years after this, Ina, king of the Weſt Saxons, arrived at Rome, on a pilgrimage to the tomb of the Apoſtles, having reſolved to renounce the world, and embrace the monaſtic life. During his ſtay in the city, he built a college for the education of youth, and the reception of ſuch of his ſubjects as ſhould undertake pilgrimages; for the ſupport of which he impoſed a tax on every houſe or family, known by the name of Rome-ſcot or Peter-pence. This tax, which, about the middle of the ninth century, was laid on the whole kingdom of England, was originally deſtined ſolely to the charitable uſes above-mentinoed, but it was afterwards converted, by the popes, to their own uſe, and levied under the denomination of a tribute to St. Peter, till Henry delivered the country of the burden. About the year 726, Leo, determined to reſtore the Chriſtian worſhip to its primitive ſtate, forbad all kinds of image-worſhip, and cauſed the edict to be promulgated through the empire. He gave notice of the ſame to the pope, requeſting his aſſiſtance in carrying the reſolution into effect, but Gregory made no ſcruple of avowing his decided oppoſition to the meaſure, and threatened the emperor with the indignation of St. Peter, ſhould he perſiſt in his projected reform. The emperor was not to be intimidated: he publiſhed his edict in Italy, but the populace was ſeriouſly againſt the innovation, and inſurrections were immediately excited, which the ſoldiery could not ſuppreſs without much miſchief and bloodſhed. Luitrand, king of the Lombards, joined the popular cry, and taking advantage of the diſturbances, made a rapid progreſs in Italy. Every where he declared his readineſs to protect image-worſhip, and every where he was received by the people as one ſent from heaven to defend the Catholic faith. Theſe events went beyond the wiſhes of the pope, he was filled with the utmoſt conſternation, well knowing that if the Lombards were ſuffered to make head in the Italian territories, he ſhould feel the weight of their yoke. He applied for aſſiſtance to Urſus, the doge of Venice, which was readily granted, and which was effectual in reſcuing the emperor's dominions from the power of the Lombards. Gregory purſued his deſign, and urged Leo, by all the eloquence in his power, to abandon his plan with regard to image worſhip; but the determination of the emperor was unalterable, and he took meaſures to get poſſeſſion of the perſon of Gregory, to prevent him from fomenting diviſions, and even rebellion among the people. Gregory obtained timely notice of his intention, and fruſtrated the deſign: he immediately thundered out a ſentence of excommunication againſt the emperor's exarch, for endeavouring to obey his maſter; and the people inſtantly took up arms, overpowered the garriſon, pulled down the ſtatues of the emperor, broke them in pieces, and openly declared that they renounced their allegiance to him as ſovereign: not ſatisfied with this, they ſome time afterwards murdered all thoſe who were adherents to the emperor's cauſe, and among others the exarch himſelf. Notwithſtanding this oppoſition, the emperor in 730 held a council of the ſenate, the great officers of the ſtate, and the biſhops who were at Conſtantinople, in which it was determined, that as it was found by experience that images could not be ſuffered to remain in churches, and idolatry prevented, they ſhould all be pulled down and deſtroyed. This being effected, he made a new effort with regard to the churches in the Weſt: he again ſolicited the pope, but Gregory's anſwer breathed a determined ſpirit of hoſtility, and was written in a ſtyle of arrogance and abuſe which was unexampled. He went ſtill farther, he aſſembled a council at Rome, conſiſting of all the neighbouring biſhops, which iſſued a decree, not only declarative of the lawfulneſs of worſhipping images, but commanding them to be worſhipped, and condemning, as heretics, all who did not worſhip them, or who ſhould preſume to teach that they were not to be worſhipped. The emperor, indignant at this aſſumption of power, ſeized on the rich patrimonies of the Roman church in Sicily and Calabria, tore from the Roman ſee the provinces of Eaſt Illyrium, and ſubjected the whole to the patriarch of Conſtantinople. By this conduct he inflicted the moſt ſevere wound in the heart of the pope, but before he had time to ripen any ſchemes of revenge, he died in 731, after he had ſat in the papal chair near ſeventeen years. From the details of his actions already given, it appears that Gregory had a zeal for exalting the power and dignity of his ſee; he was beſides arrogant and ſuperſtitious. As an author there are fifteen of his "Letters," and a "Memoir," tranſmitted to his legates in Bavaria, containing inſtructions for their guidance in managing the eccleſiaſtical affairs of that country. Theſe are inſerted in the ſixth volume of the "Collectio Conciliorum:" he was author alſo of a liturgy, which was printed, with a Greek verſion, at Paris in 1595. Moreri.

Gregory III, pope, was a Syrian by birth, became a preſbyter of the Roman church, and was much celebrated for his learning and talents as an eloquent and impreſſive preacher. Upon the death of Gregory II. he was unanimouſly choſen his ſucceſſor by the Roman people and clergy. He ſeemed determined to follow the ſteps of his predeceſſor, and declared himſelf a determined ſupporter of the worſhip of images, and he had no ſooner taken poſſeſſion of his ſee, than he wrote a letter to the emperor Leo and his ſon Conſtantine, whom he had taken as a partner in the empire, exhorting them to renounce their error, and to return, like dutiful children, into the boſom of the church. This letter he ſent by Gregory, a preſbyter of the Roman church, on whoſe zeal and firmneſs he thought he could depend, but when the preſbyter arrived, he underſtood that the emperors not only maintained their ground, but were determined to extirpate image worſhip, and thoſe who preſumed to juſtify it: he therefore thought it moſt prudent to return to Rome without acquainting them with the object of his miſſion. On his arrival, the pope was ſo exaſperated at the puſillanimity which he had ſhewn, that he called a council to determine upon ſome exemplary puniſhment, but, upon his promiſe of going back and executing his miſſion, he was pardoned. He immediately ſet out, but as ſoon as he had landed in Sicily, in his way to the imperial court, he was arreſted, his letter taken from him, and he himſelf ſent into exile. In the year 732, Gregory held a council at Rome to revenge himſelf upon the emperor for ſending his legate into baniſhment, and he procured a decree to be paſſed, eſtabliſhing the worſhip of images, and denounced excommunication againſt all who ſhould preſume to pull down, deſtroy, profane, or blaſpheme them: he even expended immenſe ſums on the purchaſe of pictures and ſtatues with which he filled the churches at Rome, and encouraged the people in the daily worſhip of them: he likewiſe cauſed relics to be brought from all parts to Rome, where he erected a magnificent building for their reception and worſhip, appointing them an appropriate ſervice, and monks to perform it. He made another unſucceſsful effort towards the converſion of the emperor, who, weary of his applications, prepared to reduce the pontiff, and the Romans who ſupported him, to obedience by force. Upon this event, the people of Rome, at the inſtigation of the pope, withdrew from all ſubjection to the emperor, and formed themſelves into a kind of republic, in which they were governed by magiſtrates appointed by their own authority, under the pope, not as prince, but only as their head. After this they were involved in hoſtilities with Luitrand, king of the Lombards, who ravaged their whole country, and even laid ſiege to the city. In this extremity, Gregory applied for aſſiſtance to Charles Martel, who refuſed to interfere till propoſals were made that the pope and Roman people ſhould ſolemnly renounce their allegiance to the emperor, as an avowed heretic, and perſecutor of the church, and that they ſhould acknowledge Charles for their protector, and confer on him the conſular dignity; and, on the other hand, Charles was to engage to protect and defend the pope, the Roman church, and the people of Rome, againſt the Lombards, and likewiſe againſt the emperor, ſhould they either be attacked or moleſted. To theſe terms Charles readily acceded, and as ſoon as Luitrand heard of the treaty he abandoned the ſiege of Rome, and retired to his own dominions. Gregory did not live long to enjoy the fruits of this policy, which contributed materially to the ſeparation of the Italian provinces from the Grecian empire. He died in 741, after a pontificate of between ten and eleven years. The only literary remains of this pope are "Seven Letters," which are to be found in the fourth vol. of the "Collect. Concil." Moreri.

Gregory IV., pope, a native of Rome, ſucceeded to the high office on the death of Valentine, in the year 827. He is commended for his extraordinary piety, of which ſome of the ſtrongeſt teſtimonies are repairing and adorning churches and monaſteries, and inſtituting the feſtival of "All Souls" day. When the quarrel took place between the emperor Lewis le Debonnaire, and his ſons, Lotharius perſuaded the pope to accompany him into France, to mediate a reconciliation between him and his father. When the pope had ſerved this purpoſe, he was permitted to return to Rome, where the beſt action performed by him that we read of, was his rebuilding and fortifying the city of Oſtia, as a protection againſt the deſcents of the Saracens. This pope died in 844, having preſided over the Roman church about 16 years. Three of his "Letters" are extant in the ſeventh vol. of the Collect. Concil. Moreri.

Gregory V. pope, whoſe original name was Bruno, was a German by birth, and a relation of the emperor Otho. He was choſen biſhop of Rome when he was but twenty-four years of age; at his ordination he aſſumed the name of Gregory, and in a very ſhort time after he ſolemnly crowned Otho emperor, who had before been only ſtyled king. He held a council in the firſt year of his pontificate, at which the emperor was preſent, and, it has been ſaid, the German electoral college was inſtituted, but it is more probable, from the evidence of hiſtory, that the origin of this college is to be referred to a later date. Upon the breaking up of the council, he returned to Germany, having firſt made the Romans ſwear allegiance to him, and obedience to the pope, but ſcarcely had the Germans repaſſed the Alps, when Creſcentius, a man of conſiderable wealth and power, perſuaded them to revolt, renounce their allegiance to the emperor, and chooſe himſelf for their head. Theſe events obliged Gregory to fly from Rome, on which occaſion Creſcentius declared the ſee vacant, and cauſed a perſon named Philagathus to be raiſed to it, who took the name of John XVII. Gregory excommunicated the uſurper, and alſo his patron, a ſentence which was confirmed by all the biſhops of Italy, France, and Germany. Soon after this Otho, urged by the intreaties of Gregory, returned to Italy, with a large army, and advanced with the pope towards Rome. At their approach, the anti-pope John took to flight, but, falling into the hands of ſome of the pope's friends, was deprived of his ſight, and otherwiſe cruelly mutilated. Creſcentius was alſo taken, and, with his accomplices, ignominiouſly executed. Gregory was now reſtored to his ſee, and one of his firſt acts was to convene a council to meet at Rome, in which the marriage of Robert, king of France, with Bertha, widow of Odo, count of Champagne, was declared inceſtuous and null. He died in the beginning of 999, having left behind him many honourable teſtimonies of the vigilance and fidelity which he had exhibited in his office. His reign was very ſhort; there are four of his "Letters" extant, in the 9th vol. of the Collec. Concil. A fifth, concerning the privileges of the abbots of Monſ. Major, may be found in the 4th vol. of "Baluze's Miſcellanea." Moreri.

Gregory VI. pope, whoſe original name was John Gratian, was deſcended from one of the moſt opulent families of Rome, and elected pope in 1044, as ſucceſſor to Benedict. Upon his acceſſion, there were no fewer than three perſons who were pretenders to the honour of being ſucceſſors of St. Peter. In this ſtate, Henry III. king of Germany, reſolved to go to Italy himſelf, and to inquire on the ſpot into the conduct of the popes, and the ſtate of the church. He aſſembled a council at Sutri, in 1046, and ſent an invitation to Gregory to preſide at this council; with which he readily complied, flattering himſelf that the king would acknowledge him for lawful pope. But when he made his appearance there, a charge was preferred againſt him of having purchaſed the pontifical dignity with a ſum of money. He confeſſed himſelf guilty of the charge, and, quitting his chair, diveſted himſelf of his pontifical ornaments before the council, and, begging forgiveneſs, renounced all claim to the throne of St. Peter. After this abdication, Henry carried him priſoner into Germany, where he ended his days. During the ſhort time that he was at the head of the church, he performed ſome very beneficial acts. Finding the lands and revenues of the ſee greatly diminiſhed by uſurpations, the roads infeſted by robbers, and other diſorders prevailing in the government, Gregory acted with ſuch vigour, that a powerful party was raiſed up againſt him by thoſe who had been accuſtomed to live by plunder. Moreri.

GREGORY VII. pope, who, by his talents, raiſed the Roman ſee to the higheſt pitch of power, is ſaid to have been the ſon of a carpenter, and to have been born at the ſmall town of Soano, in Tuſcany. His original name was Hildebrand, by which he is frequently known in hiſtory. He was educated at Rome, where he was highly eſteemed by Benedict IX. and Gregory VI., on the latter of whom he attended, when he was ſent priſoner to Germany. Upon the death of Gregory, Hildebrand embraced the monaſtic life in the monaſtery of Cluny, where he was raiſed to the poſt of prior. By Leo IX. he was created ſub-deacon, and by Nicholas II., archdeacon of the Roman church; by theſe pontiffs, and by ſome others, he was ſucceſsfully employed in ſeveral negotiations. Under the pontificate of Alexander II. he was made chancellor of the holy ſee, and had the abſolute adminiſtration of all affairs, both eccleſiaſtical and civil, as well as the entire diſpoſal of the revenues of the church of Rome. Upon the death of pope Alexander, Hildebrand appointed a faſt to be kept, and prayers to be offered up for three days together, before they ſhould proceed to the election of a new pope. While they were performing the obſequies of Alexander in the Lateran church, on the day after his death, the aſſembled people tumultuouſly cried out with one voice, "Hildebrand is pope, St. Peter has choſen him:" upon which he was immediately laid hold of and placed by force upon the pontifical throne. This election was confirmed on the ſame day by the whole body of the clergy and people. His next object was to obtain the confirmation of the king of Germany, which was a matter of no great difficulty, and immediately he took the name of Gregory, out of reſpect to his friend, Gregory VI. He was the laſt pope, the decree of whoſe election was tranſmitted to the emperor, or king, before his conſecration, or who was conſecrated in the preſence of the imperial envoy. Gregory began his reign by engaging in the moſt bold and daring ſchemes for extending the juriſdiction of the Roman ſee, and enriching the patrimony of St. Peter. He conceived the deſign, not only of emancipating the church from all ſubjection to princes, but of ſubjecting all princes to the church, and the whole church to his ſee: of conſtituting himſelf ſupreme judge and determiner of all affairs, both eccleſiaſtical and civil; the diſpoſer not only of biſhoprics and archbiſhoprics, and other eccleſiaſtical benefices, but of kingdoms and ſtates, and the revenues of individuals; and, in fact, ſole and deſpotic monarch of the earth in temporals as well as ſpirituals. Gregory was ſoon embroiled in a diſpute with Henry IV., and he omitted no meaſures which he thought likely to ſtrengthen his party, and, aided as he was by the ſuperſtition of the times, as well as by the reſentment of ſeveral princes, whom Henry had diſobliged, or who wiſhed to ſhake off his authority, he ſoon created a formidable body of confederates in his ſupport. This confederacy encouraged the pope to think of raiſing ſome other perſon to the throne inſtead of Henry, and, without heſitation, he wrote a letter to the princes, biſhops, and people of Germany, empowering them to chuſe another king, if Henry did not, by a ſincere repentance, render himſelf worthy of being replaced on the throne, which he had forfeited by his diſobedience to the apoſtolic ſee. Upon the receipt of this letter, the confederate princes and biſhops held a diet at Tribur, near Mentz, and they declared the king ſuſpended from his royal dignity, and added, that if he did not obtain abſolution before the anniverſary of his excommunication, he ſhould be excluded for ever from the throne. Henry ſubmitted to the degradation of preparing to throw himſelf at the feet of the pontiff, to ſolicit abſolution. He ſet out for Italy with his wife and infant ſon, and, after ſuſtaining uncommon hardſhips in the paſſage of the Alps, amidſt the rigours of an extremely ſevere winter, he arrived in that country. He was there ſpeedily attended by the counts and biſhops of Lombardy, who encouraged him to revenge the treatment which he had received from the pope, and offered to aſſiſt him with men and money. Gregory had, in the mean time, proceeded as far as Lombardy accompanied by the counteſs Mathilda, whoſe cloſe intimacy with Gregory afforded too much reaſon for propagating many ſcandalous reports. Upon hearing of the king's arrival, and of the reception he had met with from his Italian ſubjects, the pope retired to the ſtrong hold of Canoſa, in the dioceſe of Reggio. While remaining in this fortreſs, many German biſhops, and others who had been excommunicated for taking part with the king, repaired to him barefooted, clothed in hair cloth, to pray for abſolution and forgiveneſs, which they did not obtain without ſubmitting to ſevere penance and mortification. The pontiff enjoyed the malignant pleaſure of ſeeing the king added to the number of his humiliated ſuppliants. It was ſome time before the pontiff would admit the monarch into his preſence, and when the order was iſſued for the purpoſe, it was on the condition that he ſhould enter at the outer gate of the fortreſs without attendants; and at the next gate he was required to diveſt himſelf of the enſigns of royalty, and put on a coarſe woollen tunic, in which dreſs, and barefooted, he was ſuffered to ſtand for three whole days at the third gate, expoſed to the ſeverity of the weather, faſting and imploring the mercy of God and the pope. At length the perſons of diſtinction who were with Gregory, affected at the ſufferings of the king, began to complain of the ſeverity of his holineſs, which they ſaid was more becoming a tyrant than an apoſtolical father or judge. Theſe reports were carried to the pope, who on the fourth day admitted the king, and after much difficulty granted him abſolution. When the Lombard lords heard of the treatment which the king had met with, and his opprobrious convention, they were highly incenſed not only againſt the pope, but againſt Henry, whom they accuſed of cowardice and treachery, in ſubmitting to beg abſolution of a man whom they were determined no longer to acknowledge as their ſpiritual head. They ſeemed, at firſt, determined to depoſe him, and place his infant ſon on the throne in his ſtead, but to appeaſe their reſentment he broke the convention with the pope, reſumed his title and other marks of royalty which he had laid down, and putting himſelf at the head of his forces, he prepared to check the pope's immoderate ambition. After various ſucceſſes, in which the contending armies were alternately victorious, Henry ſummoned a council of German biſhops to meet at Mentz, who adjourned their ſeſſions to Brixen, where they were joined by many of the Italian biſhops and German and Italian princes. In this council, Gregory was accuſed of overſetting the hierarchy, and making himſelf ſole monarch of the church; encouraging ſedition and rebellion; perſecuting, excommunicating, and depoſing a peaceable king, and placing a rebel on the throne. For theſe crimes they reſolved that he ſhould be depoſed, and another choſen in his room. Notwithſtanding theſe meaſures, Gregory was able to recover himſelf, but he was again embroiled in new difficulties, and the Romans became ſo incenſed againſt the pope whom they conſidered as the author of the many calamities which they had endured, that apprehenſions were entertained of his ſafety at Rome, and he thought proper to place himſelf under the protection of duke Robert at Salerno. In that place he died in 1085, having held the ſee of Rome little more than 12 years, and leaving Europe involved in complicated calamities to which his ambition gave riſe. "He was," as Moſheim has well deſcribed him, "a man of uncommon genius, whoſe ambition, in forming the moſt arduous projects, was equalled by his dexterity in bringing them into execution; ſagacious, crafty, and intrepid, nothing could eſcape his penetration, defeat his ſtratagems, or daunt his courage; haughty and arrogant beyond all meaſure, obſtinate, impetuous, and intractable, he looked up to the ſummit of univerſal empire with a wiſtful eye, and laboured up the ſteep aſcent with uninterrupted ardour and invincible perſeverance, void of all principle, and deſtitute of every pious and virtuous feeling, he ſuffered little reſtraint in his audacious purſuits from the dictates of religion, or the remonſtrances of conſcience." He was the firſt pope who claimed the power of depoſing princes and abſolving ſubjects from their oaths of allegiance. He alſo laid claim to moſt of the kingdoms and ſtates of Europe, and by the boldneſs of his pretenſions, and his menaces of exerciſing the eccleſiaſtical authority, terrified many of their ſovereigns and rulers into acknowledgments of their being feudatories and vaſſals of the apoſtolic ſee. Three hundred and fifty-nine letters of this pope have reached our time, which are divided into nine books, and are inſerted in the 10th volume of the Collect. Concil. He is generally ſuppoſed to have been the author of "A Commentary upon the ſeven penitential Pſalms," which ſome writers have improperly aſcribed to Gregory I.: and of a "Commentary upon the Goſpel of St. Matthew," which is ſaid to be preſerved in MS. in the library at Lambeth. Bower. Moreri. Moſheim.

Gregory VIII. pope, originally known by the name of Albert de Mora, was a native of Benevento, and created cardinal by pope Adrian IV. in the year 1135. He was employed in very important miſſions, *viz.* as legate to Spain, and in the year 1172 into Normandy, where he abſolved Henry II. king of England, from the cenſures which he had incurred by being ſuppoſed in ſome degree acceſſary to the death of Thomas a Becket, but not before that monarch had ſubmitted to a diſgraceful penance. Upon the death of Urban III. in the year 1187, cardinal Albert was unanimouſly choſen his ſucceſſor, when he took the name of Gregory VIII. A ſhort time before his election, intelligence had arrived at Rome of the advantages gained by Saladin over the Chriſtians in the Eaſt, and his capture of the city of Jeruſalem. Gregory, as ſoon as he was conſecrated, wrote a letter addreſſed to the Chriſtians in the Weſt, exhorting them to contribute all in their power to the relief of their diſtreſſed brethren, and for the recovery of the holy city. He enjoined a five years' faſt, to appeaſe the anger of heaven, by abſtaining from meat on Wedneſdays and Saturdays as well as Fridays throughout the year. The labours of this pontiff were of very ſhort duration. He died within two months of his elevation. He has been applauded for his learning, eloquence, humane diſpoſition, and exemplary manners. There are three of his letters extant in the tenth vol. of the Collect. Concil. Moreri. Bower.

Gregory IX. pope, whoſe former name was Ugolin, was created cardinal biſhop of Oſtia, by pope Innocent III., and was afterwards employed on different legations to Germany and elſewhere, chiefly to preach up the neceſſity of engaging in the cruſades. He was elected pope upon the death of Honorius III. in the year 1227, when he took the name of Gregory IX. Immediately after his conſecration he commanded the weſtern biſhops to exert their authority, and oblige ſuch perſons as had taken the croſs, to ſet out without delay for the Holy Land. He wrote alſo to the emperor Frederic II. exhorting him to fulfil the ſolemn promiſes which he had made to embark a ſufficient army for the relief of the Chriſtians in the Eaſt, adding the ſevereſt menaces if he ſhould decline the undertaking, declaring that he would exert the power which heaven had put into his hands, and proceed againſt him as guilty of a breach of his vows. Frederic was obedient to the order, but having embarked with a large army, he returned in three days, alleging that the ill ſtate of his health rendered him incapable of ſo great an exertion. His excuſes were not deemed valid, the pope would hear of no apologies, and paſſed on him ſentence of excommunication, till at length the emperor embarked for Paleſtine, but not having ſued for abſolution before his departure, he was ſtill the object of Gregory's reſentment, who took every method to render his expedition fruitleſs, and to excite civil wars in his Italian dominions. Even after the emperor had, by treaty, ſecured poſſeſſion of the city and kingdom of Jeruſalem, and was preparing for his coronation there, by the patriarch he found that the prelate had been terrified by the papal emiſſaries from taking a part in the ceremony, and had alſo laid the city, and the church of the ſepulchre, under an interdict, that no divine ſervice might be performed in them during Frederic's ſtay. The German biſhops, likewiſe, who attended the emperor, partook ſo much of the patriarch's alarms, that they refuſed to perform any religious function, or even to be preſent at the coronation; ſo that Frederic was under the neceſſity of taking the crown from the altar, and placing it upon his head with his own hands. On the emperor's return in 1229, Gregory excommunicated him again; and new cauſes of complaint were continually occurring between Frederic and the pope, the former being deſirous of acting for himſelf, and the latter being fully bent upon reducing him to the moſt abject ſlavery. In the year 1241, Gregory called a general council to meet at Rome, and had ſent legates with letters to all the Chriſtian princes, entreating them to oblige the prelates in their reſpective kingdoms to repair to it. At firſt Frederic conſented to the holding of the council, and promiſed not to moleſt the biſhops who ſhould attend it. But afterwards, finding that the pope was reſolutely bent on his ruin, and that he intended to make uſe of the propoſed council for this purpoſe, and even to arm the whole Chriſtian world againſt him, he revoked his promiſes, and publiſhed a manifeſto, which was ſent through the whole of Europe, declaratory of his determined oppoſition to the pope's project. Nevertheleſs, great numbers of the biſhops did aſſemble at Genoa, in their road to Rome, who, with two cardinals and all their treaſure, fell into the emperor's hands, and the holy men were ſent priſoners to Naples. This diſappointment, together with the approach of the emperor, and his victorious army, gave ſuch a ſhock to the pope, that he was ſeized with an illneſs which put an end to his life in a few days. He had been at the head of the church nearly fifteen years, which were diſtinguiſhed by the calamities in which Italy was involved, chiefly owing to his immoderate ambition, injuſtice, arrogance, and obſtinacy. Many of his letters are to found in the eleventh vol. of the Collect. Concil.: there are alſo extant ſome fragments of his "Decretal Letters." Moreri. Bower.

Gregory X. pope, whoſe original name was Theobald, was firſt a canon in the church of Lyons; then archdeacon of Leige, and, taking the croſs, he accompanied Edward prince of Wales in his expedition into Syria. After the death of Clement IV. in 1278, the Roman ſee was vacant for nearly three years, owing to the intrigues of the cardinals, aſſembled at Viterbo, who all aſpired to the dignity themſelves, and oppoſed the election of any other. At length the magiſtrates, tired out with the delay, ordered them to be cloſely confined in the biſhop's palace, where they were ſubjected to many inconveniences, and they began daily to leſſen their allowance of proviſions. At length they choſe Theobald, who was at that time with the cruſaders in the Eaſt. Friars were diſpatched to announce to him the important news; they found him at Ptolemais, now called Acre, waiting for a favourable opportunity of paſſing to Jeruſalem, but upon receiving the decree of his election, he reſolved to embark for Italy. Before his departure he preached a ſermon to the Chriſtians at Ptolemais from theſe words, "If I forget thee, O Jeruſalem, let my right hand forget her cunning, &c." And in his ſermon he gave them very ſolemn aſſurances that he would render them every aſſiſtance in his power. He never forgot his promiſes, but both before and after his conſecration, the ſucceſs of the cruſades was an object the neareſt his heart. With this view he ſignified his intention of convening a general council at Lyons in 1274, and invited Michael Palæologus to meet it, in order to complete a work ſo neceſſary for the harmony and ſecurity of Chriſtendom. In 1273, while Gregory (a name which he aſſumed at his conſecration) was at Orvieto, Edward, who was now king of England, arrived at the city on his return from the Holy Land, and was received by the pope with every mark of eſteem and affection. On the king's complaining of the cruel murder of his couſin Henry, ſon of the duke of Cornwall by Guido, the pope inſtantly ſummoned Guido to appear before him within a limited time. Upon his paying no regard to this ſummons, he was not only excommunicated, but declared infamous, with all his deſcendants to the fourth generation, and all were anathematiſed, as equally guilty, who ſhould receive, favour, or admit him into their houſes. Finding himſelf driven from ſociety like a wild beaſt, he embraced the opportunity of the pope's travelling from Orvieto to Florence, unexpectedly to make his appearance before him, ſtripped of his garments to his ſhirt, with a rope about his neck, begging for mercy, and ſubmitting entirely to the clemency of his holineſs. Gregory gave him his life, but delivered him up to the king of Sicily to be kept in cloſe confinement till his death. Omitting the mere political events, which happened during the pontificate, we obſerve that in 1274 the general council which Gregory had ſummoned met at Lyons, and was by far the moſt numerous of any that had ever been held. The principal points which occupied its attention, were the procuring relief for the Chriſtians in the Eaſt, the union of the Greek and Latin churches, and the reſtoration of eccleſiaſtical diſcipline. To the firſt object, Gregory perſuaded the dignified eccleſiaſtics to devote a tenth of their income for the ſpace of ſix years. While the council was deliberating, Gregory depoſed the biſhop of Liege, on account of his irregularities and profligacy. This council introduced the famous conſtitution which provides that the cardinals ſhall be ſhut up in the conclave during the vacancy of the pontificate. Gregory died ſoon after the termination of the council, having held the Roman ſee four years and four months. Several of his "Letters" are extant in the eleventh volume of the "Collect. Concil." He is mentioned by hiſtorians on account of his extraordinary ſanctity, and there ſeems ſufficient reaſon to believe that he was influenced by a milder ſpirit than many of his predeceſſors. In none of them, however, is it poſſible to obſerve any conduct at all correſponding to the benevolent ſpirit of Chriſtianity: in none of them do we behold any attempt, however diſtant, to imitate the example of Chriſt, whoſe diſciples, in a ſuperior degree, they profeſſed themſelves. Moreri. Bower.

Gregory XI. pope, ſon of the count de Beaufort, and nephew of pope Clement VI. was created cardinal before he had completed his ſeventeenth year, and even then had accumulated upon him a number of rich benefices for the ſupport of his new dignity. He was honoured alſo with other high offices in the church, while he was thus young. At this time he could have made no great progreſs in literary acquirements, but it is much to his credit that he afterwards applied himſelf ſo cloſely to ſtudy, under the inſtructions of the learned Baldi and other eminent tutors, as to become one of the ableſt civilians, canoniſts, and divines of his time. Upon the death of pope Urban V. he was choſen his ſucceſſor, and was conſecrated at Avignon, which was then the ſeat of the papal reſidence, in the beginning of the year 1371, when he was about forty years old. Almoſt as ſoon as he was conſecrated, he ſent legates to mediate a peace between the kings of France and England, and wrote to thoſe princes, pathetically exhorting them to ſpare the blood of their ſubjects, and to compoſe their differences in a Chriſtian and amicable manner; but unfortunately without ſucceſs. In the ſame year he created twelve cardinals at once, and upon the ceſſion of Sicily to Frederic of Arragon, Gregory erected that iſland into a kingdom, on condition that the kings ſhould do him and his ſucceſſors homage. In 1374, the Florentines, having entered into an alliance with the Viſconti of Milan, invaded the territories of the church, making themſelves maſters of ſeveral cities, and encouraging the people to throw off the papal yoke, and reſume their liberty. Gregory's remonſtrances on this occaſion being fruitleſs, he iſſued out a bull of excommunication againſt the Florentines, which prohibited all people and nations from any communication or commerce with them; declared their eſtates forfeited, and the lawful property of thoſe who ſhould ſeize them. To his bull Gregory added other and ſtill more forcible arguments to convince the Florentines of their error. He raiſed an army of ten thouſand men which he ſent under the command of the cardinal of the twelve apoſtles; and which was ſucceſsful in ſtopping the ravages of the enemy. The Florentines, whoſe exiſtence almoſt depended on their commerce, finding their traffic entirely ſtopped by the pope's bull, thought it prudent to make an attempt at reconciliation with the apoſtolic ſee, but the terms to effect this could not be agreed on by both ſides, and hoſtilities were carried on with ardour, and chiefly in favour of the invaders. Gregory had hitherto reſided at Avignon, though he had frequently been invited to Rome. In 1377, he arrived in that city, where he was received with great marks of joy by perſons of all ranks, but the magiſtrates, though anxious for his preſence among them, refuſed to give up any part of their power. Gregory having no means of eſtabliſhing his authority, thought it prudent, and becoming his dignity, to withdraw to Anagni; but before he left Rome, he wrote ſeveral letters to England, againſt Wickliff and his doctrines, commanding the impriſonment of that worthy reformer and the ſuppreſſion of his opinions. Wickliff, however, was ſo much reſpected and beloved by the Engliſh nobility, and people at large, that the biſhops, to whom the pope's letters were addreſſed, did not dare to attempt his arreſt. Towards the cloſe of the year, Gregory, having come to ſome terms with the citizens of Rome, returned to that city, where he continued to receive many mortifications, which led him to the reſolution of removing the papal ſeat to Avignon. But before he could execute his reſolution he was taken off by death in 1378, after a pontificate of little more than ſeven years. He left behind him many letters, of which the greater part have been publiſhed by Waddingus. He is praiſed by his biographers for piety, benevolence, and humanity; he was a patron of men of letters, and was himſelf reſpectable for learning, particularly in civil and canon law. He was apt to be partial to his own relations, and paid more regard to their recommendation in the diſpoſal of preferments than to the merit of the perſons whom they recommended. Bower. Moreri.

GREGORY XII. pope, whoſe original name was Angelo Corario, was a native of Venice, and was preferred to the biſhopric of that city by pope Urban VI. By Boniface IV. he was made titular patriarch of Conſtantinople, and by Innocent VII. he was raiſed to the dignity of Cardinal in 1405. He was now eighty years of age, and upon the death of Innocent in the following year, Angelo Corario was raiſed to the chair of St. Peter, and at his conſecration took the name of Gregory XII. Peter de Luna was a rival candidate for the ſupreme honour, and aſſumed the name of Benedict XIII. Upon the conſecration of Gregory he wrote to Benedict, and the rival competitors agreed to hold a congreſs at Savona in the year 1407, accompanied by their reſpective cardinals, with a view of reſtoring order in the church. It is probable that neither of them was deſirous of this interview, but that both were ſecretly determined to uſe every means in their power to retain their dignities. Gregory refuſed to repair to the congreſs, though the meeting had been propoſed by himſelf, which gave his enemies great advantage over him; his cardinals, diſguſted at his conduct, deſerted him, and withdrew to Piſa, where they publiſhed a manifeſto in juſtification of their procedure, and an appeal to a general council, of which they ſent copies to all Chriſtian princes and ſtates. A council was held at Piſa in March 1409, which was attended by a numerous body of eccleſiaſtics, and ambaſſadors from the kings of France, England, Sicily, &c. and after fifteen ſeſſions it paſſed ſentence of depoſition againſt Benedict and Gregory, who were declared guilty of hereſy, perjury, and contumacy, and unworthy of the ſmalleſt tokens of honour or reſpect, and cut off from the communion of the church. Alexander V. was elected in their ſtead. Gregory, after ſome fruitleſs reſiſtance, formally ſent in his reſignation to the council of Conſtance, laying aſide all marks of the pontifical dignity. The council were ſo well pleaſed with his ſubmiſſion that they decreed he ſhould retain the dignity of cardinal ſo long as he lived; and that he ſhould have the precedency among the cardinals, and the title of perpetual legate of the marche of Ancona. He died at Recanati in 1417, when he was ninety-two years of age. Some of his letters are extant in the eleventh and twelfth volumes of the "Collect. Concil." He never was a man of ſhining parts; but at the time of his advancement to the head of the church, he was highly eſteemed on account of his probity, but before his death he had ſo completely loſt his character, that no credit whatever was paid to his declarations, though made in the moſt ſolemn manner. Bower. Moreri.

GREGORY XIII. pope, was born of a very reſpectable family at Bologna, in the year 1502. He was brought up to the ſtudy of the civil and canon law, made uncommon proficiency in the purſuit, and taught the ſcience in his native city with uncommon reputation for more than eight years. When he was about twenty-eight years of age, he took his degree of doctor, and was afterwards appointed judge of the court of commerce at Bologna, erected for the trial of mercantile cauſes. He removed to Rome, was employed in ſome important miſſions, admitted into the church, obtained conſiderable preferment, and on the death of Pius V. in 1572, he was unanimouſly elected his ſucceſſor, and at his conſecration he took the name of Gregory XIII. The moſt important event in the pontificate of Gregory, was the reformation of the calendar, according to a method ſuggeſted by Lewis Lilio, a Calabrian aſtronomer, which after his death was preſented to the pope by his brother. This method, which is fully explained under the word CALENDAR, and referred to in divers other articles in our work, was immediately adopted in all Catholic countries, but was rejected by the Proteſtants, and by the Greeks, who choſe rather to remain in error, than be indebted to the pope for the knowledge of the truth. In 1584, Gregory incurred the ſuſpicion of having encouraged the aſſaſſination of Elizabeth queen of England, by Parr, an Engliſh Catholic, who was detected in a conſpiracy againſt the queen's life. There was, however, no direct proof of Gregory being at all privy to the ſcheme. This pope contributed greatly to correct and amend Gratian's decretals, which he enriched with learned notes. A ſhort time before his death, he received ambaſſadors from the iſlands of Japan, where the labours of Xavier and other Jeſuits were ſaid to have been crowned with abundant ſucceſs. The ambaſſadors had a moſt flattering reception given them, and great rejoicings were ordered to be made in the city, on account of the proſpect which their appointment ſeemed to open, of triumphs to the Catholic faith in a rich and populous empire. In the midſt of theſe rejoicings Gregory was ſeized with a quinſey, which carried him off in the 84th year of his age, and the 14th of his pontificate. Several of his "Letters," "Harangues," &c. are ſaid to be in exiſtence, and preſerved in the cabinets of the curious. He was much beloved by the Romans on account of the mildneſs of his government, which, by degenerating into weakneſs, gave occaſion to numerous irregularities, and an almoſt general corruption of manners in the eccleſiaſtical ſtate. He was a zealous friend to the Jeſuits, to whom he granted many privileges, and built for their uſe, and richly endowed, the Roman college, and nearly thirty other ſeminaries in different parts of the world. Moreri. Bower. Univer. Hiſt.

GREGORY XIV. pope, ſon of a ſenator, who, after the death of his wife, embraced the eccleſiaſtical life, was made biſhop of Cremona, and appointed cardinal with the ſame title. Upon the death of Urban VII., in 1590, the conclave was divided by the pretenſions of 16 candidates for the papal chair, who were all rejected, and Nicholas Sfondrati, the ſubject of this article, was elected and acknowledged pope, and upon his conſecration took the name of Gregory XIV. He performed many humane acts as ſoon as he was ſettled in his ſee, and then endeavoured to ſignalize himſelf as the zealous defender of the Catholic faith. Among other public meaſures, he ſent bulls into France, in which he declared Henry IV. excommunicated, and threatened the nobles with eccleſiaſtical cenſures if they did not deſert his cauſe. In France theſe bulls were treated with the contempt which they merited; they were beſides declared ſcandalous and ſeditious, and ordered to be burnt by the common hangman. The pope would probably have taken meaſures to avenge the inſult thrown upon his decrees, but he died of the ſtone in the year 1592, when only in his fifty-ſeventh year, and in the eleventh of his pontificate. As a man, he is ſaid to have lived a devout and abſtemious life, and to have practiſed auſterities which would rather have ſuited a cloiſter than the ſeat of ſovereign power. He created one of his nephews cardinals, and raiſed ſix other perſons to the ſame dignity; and he alſo granted the duchy of Ferrara to duke Alphonſus, who, as he had no ſon, endeavoured to ſettle the dignity on ſome of his relations. Bower. Moreri.

Gregory XV., pope, deſcended from a noble family at Bologna, and named before his election, Alexander Ludoviſi, was born in the year 1554. He was educated among the Jeſuits at Rome, and then returned to Bologna, and ſtudied the civil law, and took his degree of doctor in that faculty. Having attained this literary honour, he went back to Rome, where he acquired the friendſhip of three popes, *viz.* Gregory XIV., Clement VIII., and Paul V. of whom the laſt appointed him archbiſhop of Bologna, and ſent him out as nuncio to adjuſt ſome differences which had taken place between the Spaniards and the duke of Savoy. For his able conduct in this difficult buſineſs he was promoted to the rank of cardinal. On his return he reſided on his dioceſe till the death of his patron Paul, in 1621, when he went into conclave with the other cardinals, and was almoſt unanimouſly choſen pope, and aſſumed the name of Gregory XV. Where his own particular ſentiments were not immediately concerned, he was a man of mild manners and very humane diſpoſition, but the whole of his papacy was marked with a violent exceſs of zeal and bigotry againſt the Proteſtants. As the Hugonots of France had, by the violation of the edict of Nantz, been driven to take up arms in their own defence, he wrote to Lewis XIII., exhorting him, by every argument in his power, to deſtroy or extirpate them; and to prove the extent of his zeal, he accompanied the letter with a bull, intended to animate the Papiſts in their ſanguinary and ſavage undertaking. He next publiſhed a bull, preſcribing a new form in the election of a pope, by which the cardinals were allowed to give their ſuffrages ſecretly, by way of ſcrutiny, by which he intended to prevent the chiefs of parties from having ſo great an influence in future elections. As a politician, he ſupported, to the utmoſt of his power, the emperor Ferdinand II. and Maximilian, duke of Bavaria, againſt the elector palatine of the Rhine, ſon-in-law of James I. of Great-Britain: by his aid they were enabled to conquer the palatinate, an event that gratified him as well by the injury which it did to the intereſts of the reformed religion in Germany, as by the ſhare which it gave him in the ſpoil of the valuable library of Heidelberg, a part of which was transferred to the Vatican. He alſo attempted the deſtruction of Calviniſm, by endeavouring to perſuade Lewis XIII. to allow the duke of Savoy to ſeize upon Geneva, the nurſery of that ſyſtem; but in this object he was diſappointed. He was likewiſe unſucceſsful in an attempt which he made to reinſtate the Jeſuits at Venice, from whence they had been baniſhed during the pontificate of Paul V. In 1622 the Turks invaded Poland with a formidable army; to reſiſt their power, Gregory ſent immenſe ſupplies of money to Sigiſmund, by which he was enabled to withſtand the barbarian power, and finally to gain a ſignal victory over them. About the ſame time the pope inſtituted the famous college, "De propaganda fide," and endowed it with ample revenues for the maintenance of perſons to be educated for foreign miſſions. Gregory endeavoured to turn to his own purpoſe the intended marriage between the prince of Wales, ſon of James I. and the infanta of Spain: he refuſed to grant a diſpenſation for the marriage, but upon very ſevere conditions, to all which James ſeemed willing to ſubmit, when the affair was ſuddenly ſuſpended by the pope's death, which happened in 1623, after he had filled the papal ſee about two years and a half. He was the author of ſome literary productions, which have been loſt, likewiſe of "Epiſtola ad Regem Perſarum Schah Abbas cum notis Hegalſoni;" and "The Deciſion of the Rota." He is highly commended for his piety and great learning, particularly in canon law, and for his charity to the ſick and poor. He was, in a certain degree, the encourager and patron of learning, and when his nephew, cardinal Ludoviſi, had formed a kind of literary academy in his palace, he was frequently preſent at their meetings, and did all in his power to promote the extenſion of ſcience and uſeful learning. He was a great friend to the Jeſuits, and canonized their founder, Francis Xavier, and by him the ſee of Paris was withdrawn from ſubjection to that of Sens, and erected into an archbiſhopric. Moreri. Univer. Hiſt. Bower.

Gregory of Neo-Cæſarea, ſurnamed *Thaumaturgus*, or Wonder-worker, from the miracles which he pretended to perform, was born at Neo-Cæſarea, in Pontus, and flouriſhed in the third century; he is uſually ſtyled a ſaint, and was known, before his converſion to Chriſtianity from Paganiſm, by the name of Theodorus. His father was a zealot for the principles in which he educated his ſon, but he cauſed him to be inſtructed in the elements of uſeful and ornamental learning. He provided for him the moſt able tutors, one of whom earneſtly recommended to his pupil the ſtudy of the Roman law, as what might be highly advantageous to him in future life. With this advice he complied, and made himſelf maſter of the principles of the ſcience. Having laid the foundation of learning at home, he ſet out upon his travels. In Phœnicia he endeavoured to improve his knowledge of law under the celebrated profeſſors of that ſcience who reſided there. He had a ſiſter married to a lawyer in high eſteem with the governor of Paleſtine, and choſen by him to be one of his counſellors. This lady was ſent for by her huſband to Cæſarea, and as the officer who came to eſcort her brought with him a greater number of carriages than were ſufficient for her and thoſe who would attend her, Gregory was induced to make one of the party. At Berytus he attended a ſchool of philoſophy lately opened by the celebrated Origen. For five years Gregory and his brother were diſciples of this great maſter, who inſtructed them in logic, phyſics, geometry, aſtronomy, and ethics. He encouraged them in reading all ſorts of ancient authors, poets, and philoſophers, whoſe tenets were not ſceptical. He reſtrained them only from ſuch as denied a deity, or a ſuperintending providence. It was during their attendance upon Origen that they became enlightened and zealous Chriſtians; he introduced them to a knowledge of the ſacred ſcriptures, and explained to them the paſſages which to their minds might appear obſcure and difficult. About the year 239, Gregory returned home: he took leave of Origen with great regret, but not before he had pronounced before a numerous auditory a panegyrical oration in praiſe of his tutor, which is eſteemed by Dupin one of the fineſt pieces of rhetoric in all antiquity, and which affords at once a proof of the writer's eminent abilities, and of Origen's excellent method of educating thoſe who were placed under his tuition. The tutor was attached to his pupil, and after his return to Neo-Cæſarea, he wrote him a letter, intending, no doubt, that he ſhould make what uſe he pleaſed of it, commending his excellent parts, which, he ſaid, qualified him either to become a Roman lawyer of the firſt rank, or a philoſopher of eminence among the Greeks, but he could rather wiſh that he would employ his great talents in the ſervice of the Chriſtian religion, which might be eſſentially benefited by his exertions. His celebrity led many to ſolicit him to open a ſchool of philoſophy in his native city, but a diffidence in himſelf led him rather to withdraw from public notice. He was next urged to undertake the office of Chriſtian biſhop, an application which he reſiſted a long time, though, at length, he was induced to accept the charge, and was ordained, according to Dr. Lardner, by Phædinus, biſhop of Amaſea, about the year 245. He was recommended to give all his exertions to his native city, which was large and populous, but immerſed in ſuperſtition and idolatry, and contained but very few Chriſtians. By his great zeal, united to much prudence, he made numerous converts to Chriſtianity, and eſtabliſhed a church which is ſaid to have been truly apoſtolic, both with reſpect to doctrine and diſcipline, and to have retained its purity, long after ſurrounding churches had admitted novelties and innovations which were a diſgrace to their religion, and inſenſibly led the way to the groſſeſt corruptions and abuſes. This church went on flouriſhing and increaſing under his care till the Decian perſecution, in the year 250, when he thought it prudent to withdraw into retirement till the ſtorm was blown over. He afterwards returned to his flock, among whom, during the remainder of his life, he diſcharged the duties of a faithful and vigilant paſtor, and was inſtrumental in bringing not only the whole city, but the dependent diſtrict into the profeſſion of Chriſtianity. He was preſent at the firſt council at Antioch, in 264, when the caſe of Paul of Samoſata was the ſubject of enquiry, and Gregory, with others, exerted themſelves in preventing any harſh meaſures from being adopted againſt him. He is thought not to have long ſurvived the meeting of this council, and to have died ſome time in the year 265. Upon the whole he was a great and good man, eminent for purity and ſimplicity of manners, zealous for the intereſts of the Chriſtian faith and profeſſion, and anxious to preſerve them unadulterated with ſuperſtitious practices. The only works of his that are extant, which are unqueſtionably genuine, are his "Oration in Praiſe of Origen," and "A Paraphraſe on the Book of Eccleſiaſtes." "A Canonical Epiſtle," conſiſting of eleven canons, is aſcribed to him by ſome authors, but it is rejected by other very able and learned critics, and is conſidered to have been added by ſome modern Greek. His pieces have been frequently printed: they were collected into one volume at Paris, in 1626; and Gerard Voſſius publiſhed an edition of them at Mentz, in 1604, in 4to. Dr. Lardner ſays there are two things to be lamented, 1ſt. That no more of this excellent man's writings have come down to us. It is plain that ſome of his writings are loſt; for Jerom ſpeaks of his epiſtles, whereas there is only one remaining. And Baſil mentions an "Expoſition of Faith," or a "Dialogue with a Gentile," which is not now in exiſtence. 2dly. That we have no hiſtory of his life, written by ſome contemporary. It may be well ſuppoſed that this apoſtolical man was chiefly employed in increaſing his church, or in building it up in knowledge and virtue, by oral inſtructions and works of goodneſs. His church continued ſtedfaſt in the faith after his death, and near the end of the fourth century the Neo-Cæſarians were all Chriſtians, having been all along to that period bleſſed with paſtors who were men of true worth. As Gregory, therefore, was an honour and ornament to the churches in his time, ſo his church continued to be an ornament to him. Lardner's Credibility, vol. iv. Moreri. Dupin

Gregory Nazianzen, was born near Nazianzum, in Cappadocia, about the year 324. His father was not brought up a Chriſtian, but, by marriage, became a convert to the true faith. His learning, piety, and many virtues, pointed him out as a proper perſon for ſuſtaining the epiſcopal character, and he was accordingly ordained, and appointed to the ſee of Nazianzum, where he officiated as paſtor for the ſpace of forty-five years. Gregory afforded early proofs of excellent natural abilities, and a ſerious turn of mind, and having made great proficiency at home, he was ſent, for farther improvement, to different public ſeminaries of learning. He was firſt placed at Cæſarea, in Cappadocia, whence he removed to Cæſarea, in Paleſtine; thence to Alexandria, and proceeded from that city to Athens, where he intended to finiſh his academical ſtudies. At the laſt named city he became acquainted with Baſil, celebrated in the church, and likewiſe with Julian, who was afterwards emperor. With the former he entered into the ſtricteſt habits of friendſhip. They lived together in the ſame houſe, united in the ſame ſtudies, and embraced the ſame tenets in religion. Having been a conſiderable time at Athens, he felt a ſtrong deſire to viſit his friends at home, and ſet out for Conſtantinople, on his journey homewards. At that city, he met his brother, Cæſarius, who had juſt arrived from Alexandria, and here he was ſtrongly urged to ſettle, but by the influence of Gregory he declined all the flattering offers made him, and returned with him to Nazianzum. Gregory, on his return, was baptized, being about thirty years of age, and from this period he ſeems to have chiefly devoted himſelf to a ſtudious and aſcetic life, practiſing the auſterities of monkery, and mixing no farther in the buſineſs of the world than was neceſſary for the management of his father's concerns. In the year 359, he viſited Baſil, in his retirement among the mountains of Pontus, and ſubjected himſelf to the ſame ſevere diſcipline which he profeſſed. He had not long enjoyed the company of Baſil, when he was ſent for in haſte to allay a ferment that had occurred in the church of Nazianzum. He ſucceeded in reconciling the differences that had occaſioned the diſcontents; entered into orders; and was ordained preſbyter. Julian, the avowed and malignant enemy of the Chriſtians, had now aſcended the throne: he publiſhed a law intended to prevent the adherents to the goſpel ſyſtem from being inſtructed in the arts and ſciences, hoping to render the followers of Chriſt barbarians; but this effort was partly defeated by the two Apollonarii; and Gregory, who wrote a number of poems in all kinds of verſe, on divers ſerious ſubjects, by which the loſs of the Greek and Roman claſſics was in ſome degree compenſated to Chriſtian ſtudents, on account of their excellencies and beauties as compoſitions. Gregory officiated for ſome years as aſſiſtant to his father in the paſtoral office. In this ſituation he was inſtrumental in promoting the election of his friend Baſil to the ſee of Cæſarea, in the year 370, a circumſtance, though well meant by Gregory, which had nearly occaſioned a rupture between the two friends; and which determined Gregory to withdraw into retirement, where he hoped he might be allowed to ſpend his life in ſtudy and religious contemplation; but by his father's earneſt entreaties he was induced to become his coadjutor in the epiſcopal office at Nazianzum, on the expreſs condition, that after his father's death he ſhould be perfectly free from all obligation to that charge. Accordingly when this event took place, in the year 374, he quitted Nazianzum, and retired to Seleucia, where he continued for a long time in a monaſtery before he returned to his native country. About the year 378 Gregory, among others, was deputed, on account of his great learning, to go to Conſtantinople to aſſiſt in defending the Catholic cauſe againſt the Arians, who were making head againſt them. When he arrived at the city he found the Catholic cauſe reduced to the loweſt ebb, ſo that the Catholics themſelves durſt ſcarcely venture to avow their opinions. At firſt he only preached in a private manner at his lodgings, but in a ſhort time the fame of his eloquence brought multitudes to hear him, and he converted the houſe in which he was into a church; to this he gave the name of Anaſtaſia, or the Reſurrection, becauſe the Catholic faith ſeemed to have its reſurrection in this particular ſpot. His ſucceſs excited the jealouſy of the Arian party, who inſtigated the populace to attack him and his hearers with clubs and ſtones, both in the ſtreets and alſo in his church. Gregory they dragged like a malefactor before the magiſtrates, accuſing him of being the cauſe of tumult and ſedition, but he was acquitted of all malice, and the perſecution which he experienced ſerved only to increaſe the number of his followers. His great celebrity attracted diſciples from diſtant parts, among whom was St. Jerom, who frequently boaſted of having had the honour and happineſs of ſtudying under ſuch a maſter. The Catholics were now ſufficiently ſtrong in number to deſire the re-eſtabliſhment of the epiſcopal office among them, and expreſſed their unanimous wiſh that Gregory would undertake it. He met with a rival in Maximus, an Egyptian Cynic philoſopher, whom he had himſelf baptized, and admitted to the lower orders of the church. This perſon contrived a ſcheme for ſupplanting him in the epiſcopal throne by intrigue and boldneſs, and engaged ſome of the Egyptian biſhops to favour his views. Gregory, on account of ill health, was obliged to quit the city for the ſake of the country air, and the confederates, unwilling to loſe any time, during the firſt night of his abſence broke into his church, and placed Maximus upon the throne. The great body of the people of all claſſes and parties in religion were indignant at this conduct: they aſſembled and with the utmoſt fury drove the intruders out of the church, who were now obliged to conſult their ſafety by flight. This attempt to ſupplant him produced much uneaſineſs in the breaſt of Gregory, and made him very deſirous of retirement, and after a time he determined to reſign a charge which involved him in increaſing troubles. He accordingly announced his intention to his people in a farewel diſcourſe, in the courſe of which he pathetically exhorted them to perſevere in the orthodox faith which he had taught them, and to be mindful of the labours and ſufferings which he had undergone for that cauſe. No ſooner had he finiſhed his exhortations, than he was ſurrounded by perſons of all ages, ſexes, and qualities, who were ſo earneſt in their entreaties that he would remain, that, at length, he promiſed not to deſert them till the eaſtern biſhops, who were expected ſoon to aſſemble at Conſtantinople, ſhould releaſe him by chooſing a more worthy perſon to occupy his place. About this period Theodoſius the Great was created a partner in the imperial throne, and avowed himſelf the ſupporter of the orthodox faith: he iſſued an edict, commanding all his ſubjects to receive the Catholic doctrine of the Trinity under the heavy penalty of being treated as heretics and infamous perſons. In the year 380 he came to Conſtantinople, where he treated Gregory with the greateſt kindneſs and reſpect, and told him that God had ſent him to give him poſſeſſion of the church, which he was ready to deliver up into his hands as a reward of his labours. A day was appointed for his inſtallation, but, at Gregory's requeſt, the ceremony was deferred for the preſent, and ſoon after having obtained the emperor's conſent, he abdicated his epiſcopal throne, and retired to his paternal eſtate, near Nazianzum, with the reſolution of ſpending the remainder of his days in ſtudious retirement, and the exerciſes of devotion. In 382, however, Gregory was ſummoned to meet the eaſtern biſhops at Conſtantinople, but he refuſed to attend, and told the fathers very plainly that experience had taught him how little good was to be expected from any ſuch aſſemblies, in which pride and ambition chiefly predominated, and which were rather calculated to widen than to conciliate differences among Chriſtians. Upon his return to his native country he was ſtrongly importuned to undertake the charge of the ſee of Nazianzum, which had continued vacant from the time of his father's death, but he could not be prevailed upon to quit his retirement, where he died in the year 389, ſuppoſed to be about the age of ſixty-five years. He was, in many reſpects, a great and a good man, and an ornament to the age in which he lived. His piety was ardent and ſincere, though not untinctured with ſuperſtition, and his morals ſtrict and regular, but partaking too much of the ſeverity enjoined by monaſtic inſtitutions. His benevolence and charity were boundleſs, and they led him to devote the whole of his income to the relief of the poor and afflicted. The works of this father conſiſt of "Sermons," "Letters," and "Poems." They were firſt publiſhed at Baſil in 1550 in Greek; but the beſt edition of them was publiſhed by Morel, in two volumes folio at Paris 1609. By Dupin he is claſſed with the moſt perfect orators of Greece, yet he admits that his ſtyle had too many antitheſes, ſimilitudes, and other rhetorical embelliſhments, which ſometimes render his oratory effeminate. Eraſmus ſays that he was diſcouraged from attempting the tranſlation of Nazianzen's works, on account of the acumen and ſmartneſs of his ſtyle, the grandeur and ſublimity of the matter, and the obſcure alluſions which are frequently interſperſed among his writings. Moreri. Dupin.

GREGORY, ſurnamed *Nyſſen*, a ſaint and father of the church in the fourth century, was a younger brother of St. Baſil, and born at Cappadocia about the year 332. He was originally intended for the eccleſiaſtical life, though for ſome time he practiſed as a profeſſor and pleader with great ſucceſs and applauſe. At the perſuaſion of Gregory Nazianzen, he was induced to relinquiſh his ſecular purſuits, and to apply with great diligence to the ſtudy of theology, and whatever was connected with it. As ſoon as he had taken orders he became as eminent in the pulpit as he had formerly been at the bar. About the year 372 he was ordained biſhop of Nyſſa, in Cappadocia, by his brother Baſil. He became diſtinguiſhed for his oppoſition to the Arian party, and on that account was baniſhed by the emperor Valens two years after his ordination. On the death of that emperor, he was recalled by Gratian and reſtored to the poſſeſſion of his epiſcopal ſee. In the year 378 he was preſent at the ſynod held at Antioch, and on his return he paid a viſit to Jeruſalem, in the hopes of gratifying his wiſhes in viewing the ſcenes of Chriſt's miniſtry, death and reſurrection, and to endeavour to allay the factions and quarrels which exiſted among Chriſtians in that city. Inſtead, however, of finding the virtues which might have been expected from the inhabitants of the Holy Land, he found "the place to be a ſink of iniquity and debauchery, the ſeat of envy, malice, adultery, robbery, murder, idolatry, poiſoning, and bloodſhed, where men aſſaſſinated each other for a trifling reward, ſo that in no place were murders ſo frequently and ſo eaſily committed." In 381 he was ſummoned to the council that met at Conſtantinople, and to him was confided the taſk of drawing up a creed, which was adopted, and is the ſame as that which has been received into the Engliſh liturgy, under the name of the *Nicene Creed*, excepting the words "and the ſon," in the part relating to the Holy Ghoſt, which were added at a later period. He was engaged in other councils, and his name appears in the liſts of the prelates who were preſent at the ſynod held at Conſtantinople in the year 394. It is not certain how long he lived after this period. He had entered into the marriage ſtate early in life, and continued to live with his wife after he had been advanced to the epiſcopal rank. His works, which conſiſt of commentaries on different parts of the ſcriptures; controverſial treatiſes; ſermons and funeral orations; biographies of diſtinguiſhed perſons, letters, &c. are many of them more like the treatiſes of Plato and Ariſtotle, than thoſe of other Chriſtians. Moreri.

GREGORY, GEORGE FLORENCE, commonly known by the name of Gregory of Tours, was born about the year 544. He was educated for the eccleſiaſtical profeſſion, was a proficient in the learning of the times, and acquired conſiderable reputation by his talents as a preacher. Being attacked by a dangerous illneſs, he paid a religious viſit to the tomb of St. Martin at Tours, which proved the occaſion of his introduction to the nobility, clergy, and other inhabitants of that city, whoſe good opinion he conciliated by his behaviour among them. So ſtrong was the impreſſion made in his favour, that on the death of Eupronius, biſhop of Tours, in 573, he was unanimouſly elected his ſucceſſor. In the year 594 he took a journey to Rome, to viſit the tombs of the Apoſtles, and to pay his reſpects to pope Gregory the Great, who received him with extraordinary marks of eſteem. He died ſoon after his return to his dioceſe, in 595, when he was in the fifty-ſecond year of his age. He was author of "The Hiſtory of France;" "The Lives of the Saints;" "Fragments of a Commentary on the Pſalms," and other pieces. The ſtyle and language of the hiſtory are harſh and inelegant, but it ſupplies the hiſtorian with facts which ſerve to fill up the chaſms in the annals of the dark ages, and which carry with them ſtrong internal marks of authenticity. The beſt edition of Gregory's works is that publiſhed at Paris in 1699. Moreri. Dupin.

GREGORY of Rimini, one of the moſt ſubtile ſchoolmen in the 14th century, was born in the city whence he took his ſurname. He became a monk of the order of the Hermits of St. Auguſtine, and taught with great applauſe in the univerſity of Paris. He was made general of his order at Montpellier in 1357, and died in the following year at Vienna. As an author, he is known by "Commentaries on the Four Books of Sentences;" "Commentaries on the Epiſtles of St Paul;" and "On the Epiſtle of St. James;" by "A Treatiſe on Uſury;" "Sermons," &c. Moreri. Bayle.

GREGORY ST. VINCENT, a Flemiſh geometrician, was born at Bruges in the year 1584. He ſtudied mathematics under Clavius, and became a member of the ſociety of Jeſuits at Rome. He acquired a very high reputation in the ſciences, was choſen to ſome high offices, and was ſelected by Philip II., king of Spain, to be mathematical tutor to his ſon, prince John of Auſtria. He died at Ghent in 1667, at the age of eighty-three. He is known as author of three learned mathematical works, of which the principal is entitled "Opus Geometricum Quadraturæ Circuli, et Sectionum Coni, decem Libris comprehenſum," 1647, in two vols. folio. In this work he ſhews, that if one aſymptote of an hyperbola be divided into parts, in geometrical progreſſion, and from the points of diviſion ordinates be drawn parallel to the other aſymptote, they will divide the ſpace between the aſymptote and curve into equal portions. Moreri.

GREGORY, JOHN, a learned Engliſh divine, was born at Agmondeſham, Bucks, in the year 1607. He received a good education, and was placed in the quality of ſervitor to Chriſt-church college, Oxford, in 1624, where he was under the tuition of Dr. George Morley, afterwards biſhop of Wincheſter. In this college he took his degrees, and was appointed one of the chaplains. In the year 1634 he publiſhed a ſecond edition in quarto, of ſir Thomas Ridley's "View of the Civil and Eccleſiaſtical Law," with notes: by this work he acquired a high degree of reputation, on account of his deep and extenſive learning, and the ſkill which he ſhewed in ancient and modern languages, Oriental as well as European. He obtained ſome conſiderable preferment in the church, particularly a prebendary in the ſee of Saliſbury. This he did not long enjoy, owing to the civil wars, in which our author was an active partiſan of the royaliſts. Being now much reduced in his means, he took up his abode at an obſcure ale-houſe near Oxford, where he remained in great privacy, devoting all his time to literary purſuits. He died before he had arrived at his fortieth year: he had, however, attained to the favour and correſpondence of many of the greateſt men of his age. In 1646 he publiſhed "Notes and Obſervations on ſome Paſſages of Scripture;" which were afterwards inſerted in the "Critici Sacri." In the year 1650 a collection of his learned tracts was publiſhed in quarto, under the title of "Gregorii Poſthuma:" he left behind him three tranſlations from the Greek into Latin, which were publiſhed in 1665, by Edward Byſhe, eſq. in his own name. They are entitled "Palladicus de Gentibus Indiæ et Brachmannibus:" "S. Ambroſius de moribus Brachmannorum:" and "Anonymus de Brachmannibus." Biog. Brit.

GREGORY, JAMES, one of the moſt eminent mathematicians of his age, was born at Aberdeen in the year 1648. He was educated at the grammar ſchool of his native town, and went through the uſual courſe of academical ſtudies in the Mariſchal college, with credit and reputation. He ſoon diſcovered a great turn for mathematical purſuits, and began, at an early age, to make improvements in the ſcience of optics. He publiſhed, in 1663, a work entitled "Optica Promota, ſeu abdita Radiorum Reflexorum et Refractorum Myſteria, Geometrice enucleata," &c. quarto. This work, which gave an account of the invention of the reflecting teleſcope, which will be deſcribed in the article TELESCOPE, immediately attracted the notice of mathematicians in all parts. About the year 1664 or 1665, Mr. Gregory came to London in order to get his inſtrument executed by ſome able hand; but being diſappointed in his object, he laid aſide his teleſcope, and went to Italy, where he reſided ſome years. In 1667 he publiſhed at Padua "Vera Circuli et Hyperbolæ Quadratura," &c. quarto, in which he announced another of his diſcoveries, that of an infinitely converging ſeries for the areas of the circle and hyperbola, by which they may be computed to any degree of exactneſs. He ſent home a copy of this work to Mr. John Collins, who communicated it to the Royal Society, where it met with much commendation. Another work, which he publiſhed in the following year, was entitled "Geometriæ Pars Univerſalis, inſerviens Quantitatum Curvarum Tranſmutationi et Menſuræ," in which he ſhewed a method of the tranſmutation of curves. Theſe works procured the author the correſpondence of Newton, Huygens, Halley, Wallis, and other moſt eminent mathematicians. Mr. Gregory was now choſen a member of the Royal Society, and upon his return from his travels he communicated to that learned body an account of the controverſy carried on in Italy concerning the motion of the earth. About the year 1668 he was appointed profeſſor of mathematics in the univerſity of St. Andrew's, an office which he held for ſix years; and in 1674 he was called to Edinburgh, to fill the mathematical chair in that univerſity; this ſituation he held but little more than a year, when, in the month of October 1675, being employed in ſhewing the ſatellites of Jupiter through a teleſcope, he was ſtruck with a ſudden and total blindneſs, and died in the courſe of a few days at the early age of thirty-ſeven. Mr. Gregory poſſeſſed an acute and penetrating genius; he was unambitious, and contented with the advantages of his ſituation as profeſſor, which conſtituted the only pecuniary reward of his eminent talents. Beſides the diſcoveries already noticed, he invented and demonſtrated geometrically, by the help of an hyperbola, a converging ſeries for making logarithms, which is recommended by Dr. Halley for practical purpoſes: he ſent to Mr. Collins the ſolution of the famous Keplerian problem by an infinite ſeries: he diſcovered a method of drawing tangents to curves geometrically, without any previous calculation, and many other things which ſhew that the moſt brilliant part of his character was that of his mathematical genius as an inventor. Biog. Brit.

Gregory, David, nephew of the preceding, an able mathematician, was born at Aberdeen in the year 1661. He was the eldeſt ſon of Mr. David Gregory who had the ſingular fortune to ſee three of his ſons all profeſſors of mathematics, at the ſame time, in three of the univerſities, *viz.* David at Oxford, his ſecond ſon James at Edinburgh, and his third ſon Charles at St. Andrew's. David, the ſubject of this article, received the early part of his education at his native place, but completed his ſtudies at Edinburgh, where he took his degree of A.M. and ſo greatly did he diſtinguiſh himſelf in ſcientific purſuits that he was elected profeſſor of mathematics in that univerſity, when he was only in his twenty-third year. About this period he publiſhed from his uncle's papers, with conſiderable additions of his own, "Exercitatio Geometrica de Dimenſione Figurarum, ſive Specimen Methodi generalis dimetiendi quaſvis Figuras." He ſoon perceived the excellence of the Newtonian philoſophy, and was the firſt who had the merit of introducing it into the ſchools by his lectures at Edinburgh. In this city he remained as mathematical profeſſor with diſtinguiſhed honour and applauſe till the year 1691, when hearing of Dr. Bernard's intention to reſign the Savilian profeſſorſhip of aſtronomy at Oxford, he went to London, and was introduced to ſir Iſaac Newton, who, conceiving highly of his talents, recommended him to be choſen a fellow of the Royal Society. Newton introduced him to the notice of Mr. Flamſtead the aſtronomer royal, and with their recommendations he was elected Savilian profeſſor, though Mr. Halley was a competitor. Their rivalſhip laid the foundation of a permanent friendſhip between theſe eminent men, and Halley afterwards was the colleague of Gregory, by obtaining the profeſſorſhip of geometry in the ſame univerſity. In 1695 he publiſhed the ſubſtance of his optical lectures which had been read at Edinburgh. This work was entitled "Catoptricæ et Dioptricæ Sphericæ Elementa," 8vo. Dr. Gregory, in 1697, gave a demonſtration of the Catenarian curve, or that curve which is formed by a chain faſtened at each end. The paper on this curve was inſerted in the "Philoſophical Tranſactions," and alſo in a work of much reputation, entitled "Miſcellanea Curioſa," as one of the nobleſt diſcoveries that had at that time been preſented to the Royal Society. The moſt celebrated work of this learned profeſſor appeared in the year 1701, entitled "Aſtronomiæ Phyſicæ et Geometricæ Elementa." This was written chiefly with the deſign of explaining ſir Iſaac Newton's geometry of the centripetal forces, as far as his diſcoveries in aſtronomy are built upon it, and to throw the aſtronomical part of his Principia into a new and more intelligible form. It was afterwards tranſlated into Engliſh, of which the ſecond edition was publiſhed in 1726, in two volumes octavo, entitled "The Elements of Phyſical and Geometrical Aſtronomy, &c." This impreſſion was reviſed and corrected by Mr. Stone. In 1703 our author publiſhed a ſplendid folio edition of the works of Euclid in Greek and Latin. He now began to prepare, in conjunction with Dr. Halley, a new edition of "Apollonius's Conics," but he had not proceeded very far in the undertaking before he was cut off by death in 1710, when only in the forty-ninth year of his age. Beſides the works of Dr. Gregory printed in his lifetime, two others were publiſhed after his deceaſe; one "A ſhort Treatiſe on the Nature, &c. of Logarithms," printed at the end of Dr. Keill's tranſlation of Commandine's Euclid; and the other "A Treatiſe of Practical Geometry," publiſhed by Mr. Maclaurin in 1745.

Gregory, James, brother of the preceding, roſe to high eminence as a mathematician. He ſucceeded his brother in the profeſſorſhip of mathematics at Edinburgh, which office he held thirty-three years with great reputation, and retiring in 1725, was ſucceeded by the celebrated Maclaurin. Charles, the other brother, was created profeſſor of mathematics at St. Andrew's, by queen Anne in 1707. This office he held with great credit thirty-two years, when he reſigned in favour of his ſon David, who ſucceeded him in 1739. He died in 1763. He publiſhed a compendium of arithmetic and algebra in Latin, entitled "Arithmeticæ et Algebræ Compendium, in Uſum Juventutis Academicæ," Edin. 1736. Biog. Brit.

Gregory, Dr. George, was a native of Ireland, but at the death of his father, who was a clergyman, and a very elegant ſcholar, the ſubject of this article was brought to Liverpool, by his mother, who was a native of Lancaſhire, where he received the elements of a learned education, which he completed at Edinburgh. He took orders in the church in 1778, and was curate at Liverpool till the year 1782, when he removed to London, and obtained the curacy of Cripplegate. In 1785 he became known as the author of a volume of "Eſſays," which had an extenſive ſale, and went through ſeveral editions; and in 1789 he publiſhed a tranſlation of Lowth's lectures "On the Sacred Poetry of the Hebrews," which was well received by the public. In the year 1804 he was preſented, through the intereſt of lord Sidmouth, by his majeſty, to the living of Weſtham, in Eſſex; he had previouſly to this obtained marks of diſtinction from the biſhop of London, which, however, were attended with very ſmall portions of emolument. Dr. Gregory did not live long to enjoy the eaſe and independence which his noble friend intended, by the preſentation of the living of Weſtham; he died March 12, 1808. Beſides, the works already mentioned, he was author of a volume of "Sermons," of the "Economy of Nature," in three vols.; of "Letters on Literature," in two vols.; and was likewiſe the editor and ſuperintendant of an "Encyclopedia of Arts and Sciences," in two volumes 4to. He was author of a Church Hiſtory in two vols. 8vo.; and of the life of Chatterton, for whoſe fate he felt the moſt ſincere commiſeration, and divers other works with and without his name. Monthly Magazine.

Gregory, John, an eminent phyſician, and profeſſor of the practice of phyſic in the univerſity of Edinburgh, was born in May, 1725. His father was profeſſor of medicine in King's college, Aberdeen; and his grandfather was profeſſor of mathematics, firſt at St. Andrew's, and afterwards at Edinburgh. Thus Dr. Gregory was the third profeſſor of his family in a lineal deſcent: and it deſerves to be remarked, that, from his great-grandfather, David Gregory, eſq. of Kinairdy, he was the fifteenth deſcendant who had held a profeſſorſhip in a Britiſh univerſity: his ſon now fills the ſame chair at Edinburgh.

John Gregory began the ſtudy of medicine at Aberdeen, and afterwards proſecuted it at Edinburgh, Leyden, and Paris. In the 20th year of his age, he was elected profeſſor of philoſophy in King's college, Aberdeen, and had at the ſame time the degree of doctor of medicine conferred upon him. In the year 1756, upon the death of his brother, Dr James Gregory, who had ſucceeded his father as profeſſor of medicine, he was elected to that chair. But about the year 1765, he left Aberdeen, and went to Edinburgh. Soon after this he was appointed profeſſor of the practice of medicine in the univerſity there, in the room of Dr. Rutherford, who reſigned in his favour. The year following, upon the death of Dr. White, he was nominated firſt phyſician to his majeſty for Scotland. Thus at the time of his death, which took place on the 10th of February, 1773, beſides very extenſive practice, he enjoyed the higheſt and moſt important profeſſional offices, which his native country could afford him.

His firſt publication, entitled "A comparative view of the ſtate and faculties of man with thoſe of the animal world," made its appearance in 1765. This production combines many juſt and original reflections, with a liberality of ſentiment ſeldom equalled. It went through four editions in two years. In the year 1770, a ſecond work of Dr. Gregory made its appearance; but without his conſent, and even contrary to his inclination. This publication was made from a ſhort-hand manuſcript taken at his introductory lectures on the practice of phyſic, and was entitled, "Obſervations on the duties and offices of a phyſician, and on the method of proſecuting inquiries in philoſophy." Although this publication contained ſo much valuable matter, that, had it appeared in a much worſe dreſs, it could have done him no diſcredit, yet he was diſſatisfied with its form; and, therefore, he ſoon after publiſhed an edition of it himſelf, in which his former ſentiments were propounded with all the advantages of a correct and elegant ſtyle. His laſt publication, "Elements of the Practice of Phyſic," was intended as a ſyllabus to his lectures; but he only lived to complete his account of the diſeaſes uſually termed febrile.

He was ſucceeded in his profeſſorſhip by the celebrated Dr. Cullen. See Duncan's Med. Commentaries, vol. i. p. 210.

GREGORY *Bay*, in *Geography*, a bay in the ſtraits of Magellan, on the S. coaſt of Patagonia.

GREGORY'S *Iſlands*, four ſmall iſlands in the Mergui Archipelago. N. lat. 10° 36'.

GREGORY'S *Sound*, a paſſage between two of the ſouth iſles of Arran, on the weſtern coaſt of Ireland, being one of the paſſages into Galway bay.

GREGOUE', a town of Africa, in the country of Whidah; four miles S. of Sabi.

GREHWEILER, a town of France, in the department of Mont Tonnerre; ſeven miles N. of Creutznach.

GREIFENBERG, a town of Lower Carinthia, on the Drave; 25 miles W. of Villaco.

GREIFFEN, a lake of Switzerland, in the canton of Zurich, five miles E. of Zurich. It is about ſix miles long and a mile broad; on one ſide the ſhores are flat or gently riſing, on the other ſide are hills richly wooded. The village of Greiffen is agreeably ſituated on a ſmall promontory, emboſomed in a wood.

GREIFFENBERG, a town of Sileſia, in the principality of Jauer; 32 miles W. of Jauer. N. lat. 50° 59'. E. long. 15° 30'.—Alſo, a town of Hinder Pomerania; 28 miles N. of Stargard. N. lat. 52 53'. E. long. 15° 12'.

GREIFFENBURG, a town of Germany, in the Ucker Mark of Brandenburg, on the Sernitz; 45 miles N.N.E. of Berlin. N. lat. 53° 8'. E. long. 14° 3'.

GREIFFENHAGEN, a town of Hinder Pomerania; 37 miles N. of Cuſtrin. N. lat. 53° 20'. E. long. 14° 36'.

GREIFFENSTEIN, a town of Germany, in the province of Solms Braunfels; ſeven miles N.N.W. of Braunfels. N. lat. 50° 37'. E. long. 8° 23'.

GREIFSWALD, or GRIPSWALD, a ſeaport town of Anterior Pomerania, on the river Rik, which is navigable to the Baltic. This town has an univerſity founded in 1456. It was formerly one of the Hanſeatic towns; 15 miles S.E. of Stralſund. N. lat. 54° 41'. E. long. 13° 22'.

GREIFSWALDE OIE, a ſmall iſland in the Baltic, off the mouth of the Oder, near the S.E. coaſt of the iſland of Uſedom. N. lat. 54° 13'. E long. 14° 3'.

GREIN, a town of Auſtria, on the N. ſide of the Danube; 62 miles W. of Vienna. N. lat. 48 16'. E. long. 14° 45'.—Alſo, a town of the Arabian Irak, on the Euphrates; 36 miles N. of Sura.

GREITZ, or GREWITZ, a town of Saxony, in the Vogtland, ſituated on a river which runs into the Elſter. In this town there are ſome ſtuff manufactures. It contains about 450 houſes; 12 miles S.W. of Zwiakau. N. lat. 50° 35'. E. long. 12° 10'.

GREKSAKER, a town of Sweden, in the province of Weſtmanland; 48 miles W. of Stroemſholm.

GREMSA. See GRAEMSAY.

GRENADA, LEWIS DE, in *Biography*, a Spaniſh Dominican monk, in the ſixteenth century, was born in the year 1504. He was probably intended for a civil life, and educated with that view, but embracing the eccleſiaſtical profeſſion, he acquired a high character for ſanctity and virtue, and was choſen to fill the moſt honourable poſts of his order. He was held in much eſtimation by the kings of Portugal and Caſtile, and was made confeſſor to queen Catherine of Portugal, ſiſter to the emperor Charles V. who was deſirous of appointing him to the archbiſhopric of Braga, an honour which he reſolutely declined: he uniformly refuſed all the offers of eccleſiaſtical preferment, and devoted his days to the auſterities of monaſtic diſcipline, and the compoſition of pious and devotional treatiſes. He died in the year 1588. His works are theological, conſiſting of "A Catechiſm," in four volumes; "A Treatiſe on Prayer," in two volumes; "Sermons," in the Latin language, in ſix volumes; and other pious and practical pieces. The greater part of them has been tranſlated from the Spaniſh and Latin into French by father Girard, and publiſhed in two volumes folio, and eight volumes 8vo.

GRENADA, in *Geography*, an iſland in the Weſt Indies, about 20 miles in extent from north to ſouth, and about 10 miles in medial breadth; the extremities gradually contracting northward and ſouthward, and particularly towards the S.W. corner. It was diſcovered and named by Chriſtopher Columbus in the year 1498; who found it inhabited by a numerous and warlike people, called Charaibes or Caribbees, among whom the Spaniards do not ſeem to have ever attempted to force a ſettlement. Theſe original inhabitants remained happy and peaceful until the year 1650, when the avarice and ambition of a reſtleſs individual devoted them to deſtruction. This perſon was Du Parquet, the French governor of Martinico, who putting himſelf at the head of upwards of 200 hardy ruffians, wantonly attacked and determined to diſpoſſeſs the unoffending natives. This atrocious act was perpetrated under the maſk of religion, and with a mixture of fanaticiſm and knavery which no honeſt mind can contemplate without indignation and horror. Notwithſtanding the injuſtice of this invaſion, the commanders adminiſtered the holy ſacrament, in the moſt ſolemn manner, to all the ſoldiers on their embarkation; and again on their landing, Du Parquet, cauſing a croſs to be erected, compelled them to kneel down before it, and join in devout prayer to Almighty God for ſucceſs to their wicked enterpriſe. Checked, however, in the progreſs of this nefarious buſineſs by ſome ſcruples of conſcience, after he had been hoſpitably entertained by the natives, he pretended to open a treaty with the chief of the Charaibes for the purchaſe of the country. Accordingly he gave the natives "ſome knives and hatchets, and a large quantity of glaſs beads, beſides two bottles of brandy for the chief himſelf," and thus, ſays Du Tertre, was the iſland fairly ceded to the French nation by the natives themſelves in lawful purchaſe! And their future reſiſtance was conſidered as contumacy and rebellion. Du Parquet, having eſtabliſhed a colony in Grenada, and built a fort for its protection, committed the government of the iſland to a kinſman, named Le Compte, who engaged in a cruel and bloody war with the Charaibes, and being reinforced with 300 men from Martinico, he proceeded to eſtabliſh and maintain his authority by maſſacres and murders, the relation of which makes even the reader to tremble. By a ſeries of ſuch enormities, the whole race of Charaibes that poſſeſſed Grenada in 1650 was ſpeedily exterminated; and the French, having deſtroyed all the natives, proceeded in the next place to maſſacre each other. Du Parquet, in the conduct and execution of thoſe meaſures by which he had gained poſſeſſion of Grenada, had ſo far impaired his fortune, that in 1656 he was under the neceſſity of transferring it to Count de Cerillac for the ſum of 30,000 crowns. This new proprietor appointed a governor, whoſe tyrannical and rapacious diſpoſition compelled the moſt reſpectable of the ſettlers to quit the country; and thoſe who remained, aſſuming the adminiſtration of juſtice, brought the governor to a public trial, and ordered him for execution. Cerillac, deriving little advantage from his purchaſe, conveyed all his rights and intereſts in Grenada, &c. to the French Weſt Indian company; whoſe charter being aboliſhed in 1674, the iſland from that time became veſted in the crown of France. The iſland, as we may naturally ſuppoſe, was very imperfectly cultivated during the progreſs of theſe revolutions and calamities; and even ſo late as the year 1700, if Raynal has been rightly informed, it contained no more than 251 whites and 525 blacks, who were employed in three plantations of ſugar, and 52 of indigo. By ſubſequent intercourſe of a ſmuggling nature with the Dutch, the circumſtances of the planters were ſomewhat improved, inſomuch that when, in the year 1762, the fortune of war made the Engliſh maſters of this and the other Charaibean iſlands, Grenada and the Grenadines are ſaid to have yielded annually, in clayed and muſcovado ſugar, a quantity equal to about 11,000 hogſheads of muſcovado of 15 cwt. each, and about 27,000lbs. of indigo. Grenada, having ſurrendered on capitulation in February 1762, was finally ceded, together with its dependencies, to Great Britain by the definitive treaty of peace at Paris on the 10th of February 1763. The chief ſtipulations of this treaty were as follow: 1ſt. That as they would become by their ſurrender ſubjects of Great Britain, they ſhould enjoy their property and privileges, and pay taxes, in like manner as thoſe of his majeſty's ſubjects of the other Britiſh Leeward iſlands. 2dly. With reſpect to religion, they were put on the ſame footing as the inhabitants of Canada, *i. e.* liberty was given them to exerciſe it according to the rites of the Romiſh church, as far as the laws of Great Britain permitted. 3dly. Such of the inhabitants of Grenada as choſe to quit the iſland, ſhould have liberty ſo to do, and 18 months ſhould be allowed them to diſpoſe of their effects. The iſland and its dependencies being thus become a Britiſh colony, two proclamations were iſſued, and general Melville was appointed governor. The crown, conceiving itſelf entitled by the terms of the capitulation to the duty of 4½ *per cent.* upon all produce exported from the newly ceded iſlands, ordered ſuch duty to be levied in Grenada, in lieu of all cuſtoms and duties formerly paid to the French king. This order occaſioned a great conſtitutional queſtion, which after much agitation was referred to a ſolemn adjudication before the judges of the court of king's bench in England. The caſe was elaborately argued in Weſtminſter hall, and lord chief juſtice Mansfield, in 1774, pronounced judgment againſt the crown: and therefore the duty in queſtion was aboliſhed, not only in Grenada, but alſo in the ceded iſlands of Dominica, St. Vincent, and Tobago.

The firſt aſſembly of Grenada met in 1765; and in 1768 the governor received inſtructions from the crown to admit two of the Roman Catholic inhabitants into the council, and to declare others to be eligible into the aſſembly on taking the oaths of allegiance and ſupremacy. Theſe inſtructions, and the meaſures which followed them, were productive of great commotions and party diviſions in the colony. The king, however, refuſed to revoke his inſtructions; upon which the moſt zealous of the Proteſtant members of the aſſembly declined attendance, ſo that it was but ſeldom that a houſe could be formed. In this ſtate of faction and perplexity the iſland continued until its recapture by the French under the count D'Eſtaing, in 1779. By the general pacification which took place in January 1783, Grenada and the Grenadines were reſtored to Great Britain.

Grenada contains about 80,000 acres of land; of which the quantity actually cultivated has never exceeded 50,000 acres. The face of the country is moutainous, but not inacceſſible in any part, and it abounds with ſprings and rivulets. To the north and the eaſt the ſoil is a brick mould; on the weſt ſide it is a rich black mould on a ſub-ſtratum of yellow clay. To the ſouth the land is in general poor, and of a reddiſh hue, which extends over a conſiderable part of the interior country. On the whole, however, Grenada appears to be in a high degree fertile, and by the variety, as well as excellence of its returns, ſeems adapted to every tropical production. The exports of the year 1776, from Grenada and its dependencies, were 14,012,157 pounds of muſcovado, and 9,273,607 pounds of clayed ſugar; 818,700 gallons of rum; 1,827,166 pounds of coffee; 457,719 pounds of cacao; 91,943 pounds of cotton; 27,638 pounds of indigo, and ſome ſmaller articles: the whole of which, on a moderate computation, could not be worth leſs, at the ports of ſhipping, than 600,000*l* ſterling, excluding freight, duties, inſurance, and other charges. The ſugar was the produce of 106 plantations, wrought by 18,293 negroes, which is rather more than one hogſhead of muſcovado ſugar, of 16 cwt. from the labour of each negro; a return, ſays Mr B. Edwards, equalled by no other Britiſh iſland in the Weſt Indies, St. Chriſtopher's excepted. The exports of 1787 were 175,548 cwt. 9 lbs. of ſugar; 670,390 gallons of rum; 4,300 gallons of melaſſes; 8,812 cwt. 2 qrs. 4 lbs. of coffee; 2,716 cwt. 3 qrs. 18 lbs. of cacao; 2,062,427 lbs. of cotton; 2,810 lbs. of indigo, and miſcellaneous articles; ſuch as hides, dyeing wood, &c. to the amount in value of 64,545*l.* 0*s.* 8*d.*; and the total value of all, according to the current prices in London, 614,908*l.* 9*s.* 3*d.*

This iſland is divided into ſix pariſhes, *viz.* St. George, St. David, St. Andrew, St. Patrick, St. Mark, and St. John; and its chief dependence, Cariacou, forms a ſeventh pariſh. Since the reſtoration of Grenada to Great Britain in 1783, an iſland law has been obtained for the eſtabliſhment of a Proteſtant clergy. This act, which paſſed in 1784, provided ſtipends of 330*l.* currency, and 60*l.* for houſe-rent *per annum*; for five clergymen, *viz.* one for the town and

and pariſh of St. George, three for the other five out pariſhes of Grenada, and one for Cariacou. Beſides theſe ſtipends, there are valuable glebe lands formerly appropriated to the Roman Catholic clergy, when that was the eſtabliſhed religion of Grenada, which became veſted in his majeſty as public lands on the reſtoration of the iſland to the Britiſh government, and which, it is ſaid, have been applied by the colonial legiſlature, with the conſent of the crown, to the further ſupport of the Proteſtant church, with ſome reſerve for the tolerated Romiſh clergy. The capital of Grenada, ſoon after the ceſſion of the country to Great Britain by the peace of Paris, is called *St. George*, which ſee. The other towns in Grenada are, properly ſpeaking, inconſiderable villages or hamlets, which are generally ſituated at the bays or ſhipping places in the ſeveral out-pariſhes. The pariſh town of Cariacou is called Hillſborough. Grenada has two ports of entry, with ſeparate eſtabliſhments, and diſtinct revenue officers, independent of each other; one at St. George, and one at Grenville bay, a town and harbour on the eaſt, or windward ſide of the iſland. The whole population of Grenada and the Grenadines has decreaſed conſiderably ſince theſe iſlands firſt came into poſſeſſion of the Engliſh. In the year 1771, the number of white inhabitants was ſomewhat more than 1600; in 1777, they had decreaſed to 1300, and at a later period they were ſuppoſed not to exceed 1000, of which about two-thirds are men able to bear arms, and incorporated into five regiments of militia, including a company of free blacks or mulattoes attached to each. There are likewiſe about 500 regular troops from Great Britain, which are ſupported on the Britiſh eſtabliſhment. Beſides the regular troops ſent from Great Britain for the protection of Grenada, there are in its garriſon three companies of king's negroes, which came from America, where they ſerved in three capacities, as pioneers, artificers, and light dragoons. In Grenada they form a company of each, and are commanded by a lieutenant of the regulars, having the rank of captain. The negro ſlaves have alſo decreaſed. In 1779 they were ſtated at 35,000, of which 5000 were in Cariacou and the ſmaller iſlands. In 1785 they amounted to no more than 23,926 in the whole. The free people of colour amounted in 1787 to 1,115. To prevent the too great increaſe of perſons of this claſs, every manumiſſion is, by an act of the iſland, charged with a fine of 100*l.* currency, payable into the public treaſury. The evidence of theſe people, whether born free or manumitted, is received in the courts of this iſland, on producing proof of their freedom; and they are tried on criminal charges in the ſame manner as whites. They are alſo allowed to poſſeſs and enjoy lands to any amount, provided they are native-born ſubjects or capitulants, and not aliens. The governor is, by virtue of his office, chancellor, ordinary, and vice-admiral; and preſides ſolely in the courts of chancery and ordinary, as in Jamaica. His ſalary is 3,200*l.* currency *per annum*, which is raiſed by a poll-tax on all ſlaves; but in all caſes of abſence beyond twelve months, the ſalary ceaſes and determines. N. B. The currency of Grenada, or rate of exchange, is commonly 65*l. per cent.* worſe than ſterling. The council of Grenada conſiſts of 12 members, and the aſſembly of 26. A free-hold, or life-eſtate of 50 acres, is a qualification to ſit as repreſentative for the pariſhes, and a free-hold, or life-eſtate, in 50*l.* houſe-rent in St. George, qualifies a repreſentative for the town. An eſtate of ten acres in fee, or for life, or a rent of 10*l.* in any of the out-towns, gives a vote for the repreſentatives of each pariſh reſpectively; and a rent of 20*l. per annum*, iſſuing out of any freehold or life-eſtate in the town of St. George, gives a vote for a repreſentative of the town. The law-courts in Grenada, beſides thoſe of chancery and ordinary are the court of grand-ſeſſions of the peace held twice a year, *viz.* in March and September; the court of common-pleas, conſiſting of one chief and four aſſiſtant juſtices, whoſe commiſſions are during pleaſure, the chief juſtice being uſually appointed in England, with a ſalary of 600*l.* *per annum*, and the others being commonly appointed by the governor without any ſalary; the court of exchequer, lately grown into diſuſe; the court of admiralty for the trial of all prize-cauſes of capture from enemies in war, and of revenue-ſeizures in peace or war, having one judge of admiralty and one ſurrogate; and a court of error, compoſed of the governor and council, for trying all appeals of error from the court of common-pleas. The common and ſtatute-laws of England are conſidered as extending to Grenada in all applicable caſes, not provided for by the laws of the iſland. N. lat. 12° 10′. W. long. 61° 30′. Edwards's Hiſt. of the Weſt Indies, vol. i.

GRENADA, or *Granada.* See GRANADA.

GRENADA. See GRANADO.

GRENADE, a town of France, in the department of the Landes, and chief place of a canton, in the diſtrict of Mont-de-Marſan; ſeven miles E. of St. Séver. The place contains 1330, and the canton 7563 inhabitants, on a territory of 195 kiliometres, in eleven communes.—Alſo, a town of France, in the department of the Upper Garonne, and chief place of a canton, in the diſtrict of Toulouſe; 12 miles N. N. W. of Toulouſe. The place contains 3500, and the canton 9142 inhabitants, on a territory of 232½ kiliometres, in 13 communes.

GRENADIER. See GRANADIER.

GRENADIER, in *Ornithology.* See LOXIA *Orix.*

GRENADIN. See FRINGILLA *Granatina.*

GRENADINES, or GRENADILLAS, in *Geography*, a cluſter of iſlands in the Weſt Indies, amounting in number to more than 20, ſituated between Grenada and St. Vincent, and producing cotton, coffee, indigo, and ſugar. Cariacou is the principal. Theſe iſlands formerly appertained to the government of Grenada; but by an arrangement of the Britiſh adminiſtration, a line of diviſion paſſes in an eaſt and weſt direction, between Cariacou and Union iſland. The former of theſe, and ſome ſmaller iſlands ſouth of it, are all that are now comprized in the Grenada government: Union iſland, with all the little iſlands adjoining, to the north, being annexed to the government of St. Vincent. See CARIACOU and RONDE.

GRENAILLE, a name given by the French writers to a preparation of copper, which the Chineſe uſe as a red colour in ſome of their fineſt china, particularly for that colour which is called *oil-red*, or *red in oil.* The china-ware coloured with this is very dear. The manner in which they procure the preparation is thus: they have in China no ſuch thing as ſilver-coined money, but they uſe in commerce bars or maſſes of ſilver; theſe they pay and receive in large bargains; and among a nation ſo full of fraud as the Chineſe, it is no wonder that theſe are often adulterated with too great an alloy of copper. They paſs, however, in this ſtate in the common payments. There are ſome occaſions, however, ſuch as the paying of the taxes and contributions, on which they muſt have their ſilver pure and fine; on this occaſion they have recourſe to certain people, whoſe ſole buſineſs it is to refine the ſilver, and ſeparate it from the copper and the lead it contains. This they do in furnaces made for the purpoſe, and with very convenient veſſels. While the copper is in fuſion, they take a ſmall bruſh, and dip the end of it into water; then ſtriking the handle of the bruſh, they ſprinkle the water by degrees upon the melted copper; a ſort of pellicle forms itſelf by this means on the ſurface of the matter, which they take off while hot with pincers of iron, and immediately throwing it into a large veſſel of cold water, it forms that red powder, which is called the grenaille; they repeat the operation every time they in this manner ſeparate the copper; and this furniſhes them with as much of the grenaille as they have occaſion for in their china works. Obſervations ſur les Coûtumes de l'Aſie, p. 309.

GRENAHEN, in *Geography*, a town of Switzerland, in the Valais; 25 miles E. of Sion.

GRENAT, in *Ornithology*. See Trochilus *Auratus*.

GRENIER, in *Geography*, mountains of Hindooſtan, in the country of Guzerat, near Junagur.

GRENNA, a town of Sweden, in the province of Smaland; 10 miles N.N.E. of Jonkioping.

GRENOBLE, an ancient, large, and well-built city of France, and capital of the department of Iſere, ſituated in a marſhy but fruitful plain, at the foot of a hill, near the conflux of the river Iſere. Before the revolution it was the capital of Dauphiny, the ſee of a biſhop, and the ſeat of a parliament. It was the ſcene of many cruelties in the religious wars, A.D. 1562. It is divided by the river Iſere into two unequal parts, the largeſt of which is regularly built. Its manufactures are cloth, hats, gloves, &c. The number of its inhabitants is 23,500 in 3 cantons, on a territory of 265 kiliometres, in 26 communes. To the north are the ruins of a citadel, on an eminence, which commands an agreeable proſpect of the town, the banks of the Iſere, and ſeveral fertile vallies. In a rugged valley, watered by the rapid Drac, about 5 leagues S. of Grenoble, are the mineral ſprings of La Motte, highly eſteemed as a remedy for fluxes and all diſorders of the ſtomach, but little uſed on account of the difficult acceſs to them. Four leagues N. of Grenoble is Le Grand Chartreuſe, a famous Carthuſian monaſtery, founded A.D. 1086, conſiſting of an excellent library, and many apartments, on an eminence environed by rugged precipices of difficult acceſs. N. lat. 45° 11′ 59″. E. long. 5° 43′ 10″.

GRENOUILLES, Les, a cluſter of rocks in the Weſt Indian ocean, about 36 miles S.E. from point Morand, in the iſland of Jamaica. N. lat. 17° 32′. E. long. 76 32′.

GRENVILLE, a town of Nova Scotia. See Granville.

Grenville, a county in Upper Canada, bounded on the E. by the county of Dundas, on the S. by the river St. Lawrence, and on the W. by the townſhip of Elizabeth town, running N. 24° W. till it interſects the Ottawa or Grawl river, and thence deſcending that river until it meets the north and weſternmoſt boundary of the county of Dundas. This county comprehends all the lands near to it in the river St. Lawrence.

Grenville's *Canal*, a channel of the N. Pacific ocean, which ſeparates Pitt's Archipelago from the coaſt of New Cornwall.

GRENZHAUSEN, a town of Germany, in the county of Wied; 5 miles N.E. of Coblentz.

GREPPEN, a town of Switzerland, in the canton of Lucerne; 5 miles E. of Lucerne.

GRES, Cape au, a promontory on the E. ſide of the Miſſiſippi, in the N.W. territory, 3 leagues above the Illinois river, and the tract of country ſo called extends 5 leagues up that river.

GRESHAM, *Sir* Thomas, in *Biography*, an eminent London merchant, ſon of ſir Richard Greſham, who was raiſed to the high office of lord mayor of the city of London, was born in 1519. He received an academical education at Cambridge, but being deſigned to follow the commercial buſineſs of the family, he was bound apprentice to his uncle ſir John Greſham, and thus became a member of the Mercers' company. His father was agent of the king's money concerns at Antwerp, and Thomas expected to be his ſucceſſor in this buſineſs, but the preference was given to another perſon, by whoſe miſmanagement they were brought into a deplorable condition. Recourſe was now had to the ſubject of this article, who was ſent over in 1532 by the regency in the minority of Edward VI., in order to retrieve them. In this affair he exerted ſo much talent, that in two years he was able to pay off the whole of a loan bearing enormous intereſt, and raiſed the king's credit to the moſt reſpectable rank. At the acceſſion of Elizabeth, he was for a time deprived of his office, but it was reſtored to him again, and he continued in it as long as he lived. He alſo received at the hands of his ſovereign the honour of knighthood. He tranſacted many important pecuniary negociations of that long and glorious reign, and was a moſt ſpirited promoter of the infant manufactures of the kingdom, thoſe of ſmall wares in particular being eſtabliſhed chiefly through his means. His own property, derived by inheritance, with that acquired by his induſtry and talents, made him the richeſt ſubject in the metropolis, and he made uſe of his wealth to noble and extenſively beneficial purpoſes. In 1564 he had the misfortune to loſe his only ſon, and he fell upon the means of diverting his grief on this melancholy occaſion by public undertakings. The firſt deſign of building an exchange for merchants, in imitation of that of Antwerp, was entertained by his father. Sir Thomas carried the plan into effect, and completed the noble building in three years. (See Royal *Exchange*.) When the troubles in the Low Countries interrupted the accuſtomed loans to the crown from Antwerp, ſir Thomas adviſed the miniſter to apply to the merchants of his own country, and this may be conſidered as the commencement of the immenſe advances ſince made to the crown from the ſame body. Sir Thomas Greſham next determined to beſtow a part of his wealth in founding a college for the ſciences in his native city. The principal people in the univerſity of Cambridge endeavoured to diſſuade him from thus eſtabliſhing a rival inſtitution; but his determination was fixed. He deviſed by will his houſe in Biſhopſgate-ſtreet for the purpoſe of being converted into habitations and lecture-rooms for ſeven profeſſors, or lecturers on the ſeven liberal ſciences, who were each of them to receive a ſalary out of the revenues of the Royal Exchange. Theſe lectures are ſtill given in apartments in the Royal Exchange, whenever there are a ſufficient number of auditors aſſembled to call for the exertions of the lecturer. The ſubjects of the lectures are *divinity*, *law*, *phyſic*, *aſtronomy*, *geometry*, *muſic*, and *rhetoric*. Sir Thomas endowed many public charities. He died ſuddenly in his own houſe in the year 1579, and was buried in a ſumptuous manner in the church of St. Helens, Biſhopſgate-ſtreet. He had expended large ſums of money in erecting corn, oil, and paper-mills upon the ſtream of the Brent, near his favourite villa at Oſterly-park. Biog. Brit.

Gresham *College*. See College.

GRESHOLM, in *Geography*, a ſmall iſland of Denmark, in the Categat; 4 miles N.E. of Leſſoe.

GRESI, a town of Turkiſh Armenia; 28 miles S.E. of Rizeh.

GRESLEY's Canal, is an inland navigation in Staffordſhire, near Newcaſtle-under-line, made in purſuance of an act of 15 Geo. III. To the account given in our article

CANAL we have here only to add, that in 1805 the Nantwich and Newcaſtle rail-way was propoſed, to connect with this canal, at Dale's pool.

GRESLING, in *Ichthyology*, a name given by the Germans to the *gobius fluviatilis*, or *common gudgeon*, which is very frequent in their ſmaller rivers.

GRESNICH, in *Biography*, a modern German compoſer of the Italian ſchool, who has compoſed ſeveral ſucceſsful operas in Italy, and whoſe capital *bravura* airs were frequently ſung in England by madame Mara, for whoſe abilities of execution we believe they were originally compoſed.

GRESSEN, in *Geography*, a town of Samogitia; 20 miles N.N.E. of Miedniki.

GRESSET, JOHN BAPTIST LEWIS, in *Biography*, born at Amiens in the year 1709, was educated among the Jeſuits, and from this retreat he ſent forth ſome poems, which poſſeſſed all the eaſe and delicate pleaſantry that could have been looked for from the pen of a man of the world. Theſe were entitled "Ver Vert," a very pleaſing tale; his epiſtles of "La Chartreuſe;" "Les Ombres," and many others. His reputation as a poet was the cauſe of his quitting the ſociety, and fixing his reſidence in the metropolis. He now tried his powers in dramatic compoſition; in tragedy he had very little ſucceſs, but his comedies were better received; and that entitled "Mechant," repreſented in 1747, raiſed him to the firſt rank of writers in this claſs. It was regarded as a maſterpiece in that ſpecies of comedy which paints manners with truth and force, without being highly comic. Greſſet was admitted a member of the French academy in the year 1748. He grew weary of a literary life, ſeemed to doubt of the propriety of theatrical exhibitions, and ſoon after renounced the ſtage, by a letter, in which he diſplayed the dangers attending public ſpectacles. He returned to Amiens, where he obtained a poſt under government, married a lady with a good fortune, and paſſed the remainder of his life in a manner which acquired him the eſteem and reſpect of his fellow citizens. In 1775 he reviſited the metropolis, and had the honour, as director of the French academy, to compliment Lewis XVI. and his queen on their acceſſion to the throne. His diſcourſe on this occaſion, which was printed, was a ſevere ſatire on the vices and follies of the metropolis. He died in June 1777, having received, ſome time previouſly to this, letters of nobility, and having been likewiſe appointed hiſtoriographer of the order of St. Lazore. Greſſet is placed between Chaulieu and Voltaire for the graces of light poetry: he is perhaps the firſt at the theatre for elegance of verſification in comedy, and his morals were as pure as his ſtyle. Gen. Biog.

GRESSIN, in *Geography*, a town of Hinder Pomerania; 14 miles S.E. of Belgard.

GRESTEN, a town of Auſtria; 9 miles N.E. of Bavaria Waidhoven.

GRETA, a river of England, which riſes in the N.W. part of Yorkſhire, and runs into the Tees, about 4 miles below Bernard's Caſtle, in Durham.

GRETNA GREEN, a mean village of Scotland, in the ſhire of Dumfries, 8 miles from Carliſle, and 82 from Edinburgh, at the S.E. extremity of the county, near the W. bank of the Sark, and bottom of Solway firth; famous for the clandeſtine marriage of parties from England, celebrated by perſons who have no right to marry, or to exerciſe any part of the clerical function; becauſe it is out of the juriſdiction of the marriage act.

END OF VOL. XVI.

Strahan and Preſton,
New-Street-Square, London.
